The Development of Land Cover Accounts and Environmental Indicators for the Forest and Biodiversity for the 4 CEE Countries: Final Report

Introduction

This report is a second part of the work done by the European Topic Centre on Terrestrial Environment with the support of the European Environment Agency on *Integration of geographical and statistical data in the environmental accounting framework.* This part is geographically focused on the 4 Central and Eastern European (CEE) countries, the Czech Republic, Hungary, Slovakia and Romania, and thematically on forest and forest biodiversity issues. In evaluating the contribution of this study to the general development of the environmental accounts, the outputs should be considered alongside those of a parallel study on the coastal zones in Europe, also funded by the present contract, which uses the same concepts and similar data and analytical methods to address a different set of environmental issues.

The aims of this part of the work were as follows:

i. To produce a set of environmental indicators based on CORINE Land Cover data using the concept of land cover accounting as a decision making and integrating framework for forest issues and biodiversity

ii. To investigate the feasibility of producing more general land cover account at the European scale

iii. To raise general awareness of land cover accounts concept as a framework for indicator development.

The structure of this report is as follows. This introductory chapter reminds the common information on the background, the context of the study and the general concepts presented already in coastal part of the study with some amendments reflecting specifics of forest and biodiversity issues. In Part 2, the data sources used for the study are described. In Part 3, the construction of the basic account are described in detail. The analytical methods used to create the basic accounts are summarised here and the results and first assessment are provided. Similarly, in Parts 4, the theoretical concepts underlying the construction of the targeted account are described in detail, methods used to create the targeted accounts are presented and results summarised. Part 5 presents the contribution of forest accounting for forest indicators development Finally, the outputs of this study and the implications of this project for subsequent work are discussed. Detailed versions of all accounts are included in Annex.

Part 1: Background, Context and General Concepts

1.1 Background and Context for Study

The need to develop and apply systems of environmental accounting has been widely recognised by the international community. In the 1990s for example, *Agenda 21* highlighted the need for reform of national systems of economic accounting to ensure that the environmental impacts of economic activity are to be expressed clearly. As a result subsequent work has sought to develop different ways of 'taking the environment into account'.

A key stimulus to recent work has been activities of the 'London Group' of the United Nations Statistical Division[1], which aims to provide an annual forum for leading countries and international organisations to exchange practical and conceptual expertise with respect to the development of environmental accounts linked to the System of National Accounts. Their goal is to play a leading role in defining international standards in the theory and practice of environmental accounting.

Reviews of approaches provided by the London Group and others broadly leads to the definition of environmental accounting as any method that records changes, directly or indirectly, in the quantity or quality of the environment where change is expressed in monetary or physical units. In this sense two broad approaches can be recognised:

- Monetary Environmental Accounting (MEA), in which changes in the status of environmental assets or resources are given monetary value.
- Physical Environmental Accounting (PEA), in which changes in the status of environmental assets or resources are expressed in appropriate physical units, rather than in non-monetary terms.

This study focuses on one type of PEA, namely *Land and Ecosystems Accounts*[2] (LEAC). These accounts deal with changes in land cover and land use and seek to trace the wider implications environmental, social and economic implications of these transformations.

The methodology, which PEA is based on, has been developed in a consistent way since mid-90's, as the result of a pilot study sponsored by the UNECE and published by IFEN[3] in 1995.

2 SEEA 2000, draft version, Chapter IX, section C, *London Group website and CBS of the Netherlands, papers of the London Group meeting, Voorburg, 7-11 May 2001* and Emission Structure Information System : Physical Accounts for Land cover /Land use and related Changes in Artificiality of Land and Biodiversity" *report for Eurostat by IFEN with contributions from StBA of Germany and the University of Nottingham, 1997.*

3 Physical Environmental Accounting : Land Use/ Land Cover, Nutrients and the Environment, *UN-Economic Commission for Europe, Etudes et Travaux n°4, IFEN, Orléans, France, 1995.*

The results were presented, the following year, with 3 communications at the IARIW Special Conference on *Environment accounting in theory and practice* in Tokyo[4].

The research continued in the context of a task force at Eurostat with a set of 3 case studies in France, UK and Germany[5]. These were designed to assess:

- the possibility of building up accounts on CORINE Land Cover (an assessment in Franche-Comté, France);
- the benefits for reporting in an accounting framework an the stratification of land requested (from the Countryside Survey, UK);
- the linkages of land accounts and sectors (Germany)

As a result of such work, the Eurostat working group6 argued that *"... land accounting techniques, with linkages to both human activities and natural processes, can be regarded as a useful tool for responding to a number of issues set out by policy objectives*". It was suggested that these included:

- Biodiversity and habitats
- Intensity of land use
- Urbanisation and, in general, changes in land use
- Linear features
- Spatial fragmentation and contiguity
- Soil sealing
- Tranquillity and resilience of ecosystems
- Possibly net primary production and climate change

Initial research on LEAC has led on to the drafting of the Section C (Land and ecosystem accounts) in Chapter VII (Specific resource accounts) of the new SEEA (System of Environmental and Economic Accounting, SEEA 2000, draft version)[7].

7 SEEA, System of Environmental and Economic Accounts, rev. 2000, Chapter 8, Section F Land and Ecosystems Accounts, §8.336 to §8.399 – Draft prepared by the London Group on Environmental

Despite such progress, while the usefulness of the overall approach to LEAC has been established, further empirical applications of the techniques are required to demonstrate the value of Europe-wide applications. When the Topic Centre on Terrestrial Environment of the EEA was created end of 2001, EUROSTAT proposed to test the draft "LEAC" methodology, in view of its possible implementation with CORINE land cover data and European statistics in context of undergoing I&CLC2000 project resulting in CLC database update in 2004. Two case studies were agreed upon for two areas were CLC data on change were already available: the European coast (LACOAST project of the JRC, 1975-1990) and 4 countries of Central Europe (Czech Republic, Slovakia, Hungary and Romania) which have made an assessment of retrospective CLC for 1975 for the EEA[8], and also have available the PHARE inventory of 1990.

This Report follows the first study focused on the coastal zones of Europe and describes the LEAC approach, which can be useful in the context of understanding land use and land cover changes on country or European-wide level, in particular referring to forest and biodiversity issues. Some adjustments to methodology have been considered working with multi-country wide data and the results are published further in Parts 3, 4 and Annex.

1.2 Justification and contribution of the project

The justification for this project lies in the potential contribution of environmental accounts to tasks such as preparing 'state of the environment reports', and the development and appraisal of environmental policy. In general terms, the main purpose of preparing accounts is to draw up a 'balance sheet' for a set of environmental resources that shows both their current stock and how these stocks are changing over time. The analysis of these temporal changes is, however, particularly significant because accounts seek go beyond the simple plotting of the stocks of resources over time in a simple graphical manner to look at the processes that transform those resources. Thus the construction of 'flow accounts' is particularly significant in this context.

The idea of a flow account, as they might be applied to problem of understanding land cover change is illustrated in Figure 1.1. If the stocks (area) of a given land cover resource, such as woodland, are tracked over time, the change observed is determined by the balance of gains and losses to the initial stock. While in some contexts, an analysis of the net change in area of woodland may be important, it is clearly just as important to understand how the stock 'turns over', because the flux of land into and out of this land cover category may also affect the quality of the woodland resource that is carried forward over time. In terms of making a judgement about the sustainability of the net woodland change, for example, the quality of the woodland resource at the end of the accounting period would only be maintained if the new woodland gained compensated in some way for the woodlands lost.

Looked at in this way, flow accounts in particular provide a powerful set of tools for both monitoring environmental resources, and for evaluating different policy options. They can, for

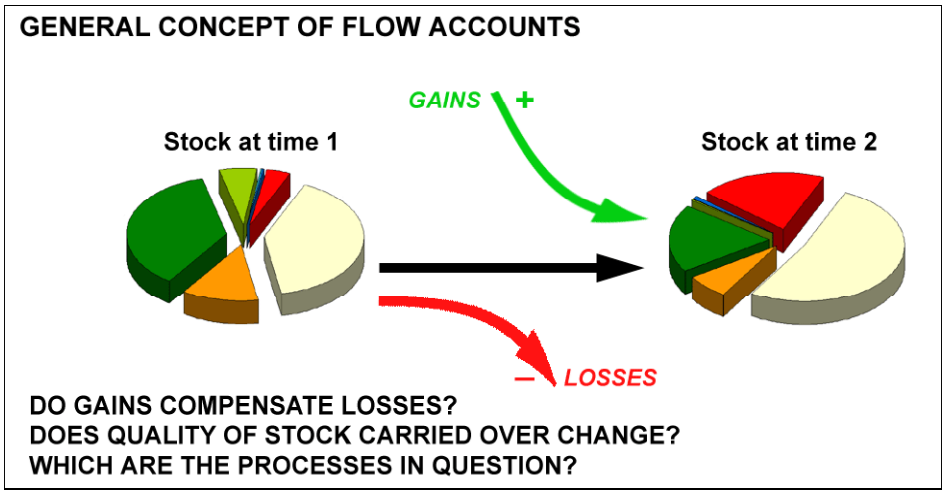
---

Accounting and submitted to the UN Statistical Commission in March 2001 – forthcoming publication by UN.

8 PTL/LC (1999) - Inventory and Analysis of Major Land Cover Changes in Central and Eastern Europe over the Past 20 Years, Topic Report, EEA Phare Topic Link on Land Cover (PTL/LC), GISAT

example, provide a systematic basis for the development of indicators of change. In the context of illustration provided by Figure 1.1, for example, the proportion of the initial stock carried over from time 1 to time 2 could serve as a potential sustainable development indicator. In addition, by expressing the flows into and out of the different resource categories in a clear and consistent and comprehensive way, targets for future resource levels can be identified, together with the potential costs of encouraging or preventing certain types of transformation.

Figure 1.1 – General concept of flow accounts



The application of environmental accounting techniques is particularly appropriate in the context of forests sustainable development and its spatial dimension – one of priority policy issues at EU level. Forests are a complex and multifunctional natural asset which is at the same time an economic resource for timber, other wood products and non-wood products, an amenity of high value for urban as well as rural population, a protection of soil against erosion and a major reserve of biodiversity, in itself as well as due to its interfaces with other types of landscapes. Forests are unevenly distributed over Europe and their biological characteristics vary from the North to the South. Ahead of a possible over-harvesting and landtake by urbanisation, pressure on forests relate to their increasing fragmentation by transport networks, acidification and soil contamination, selection of species with a unique interset in timber and pulp production and the multiplication of forest fires. Sustainable forests policies aim at a balanced management.

Europe's forest biodiversity is under pressure, with a significant proportion of the protected species and habitats under European Directives being forest-related. Forestry and biodiversity issues are therefore among the priorities, resulting in the Convention on Biological Diversity, the Forest Principles and a forest component of *Agenda 21*. In Europe, activities to implement these commitments have resulted, for example, in the `*Environment for Europe*' process endorsed by the Environment Ministers and the Ministerial Conferences for Protection of Forests in Europe (MCPFE)[9] set up by the Forest Ministers. MCPFE has developed a set of Pan-European Criteria, Indicators and Operational Level Guidelines for Sustainable Forest Management. The EU has implemented these concerns in, for example, *the Habitats Directive*[10], *the Community Forestry Strategy*[11] *and Community Biodiversity Strategy*[12] and,

9 MCPFE - www.minconf-forests.net

10 EU Habitats Directive 92/43/EEC

11 European Community strategy and action programme for the forestry sector - COM(88) 255

most recently, *the Biodiversity Action Plans*[13] and *the 6th Environmental Action Plan (EAP)*[14].

The need to understand patterns of land use and land cover change are recognised as essential elements of future strategies designed to overcome the problems with biodiversity loss through sustainable management of European forests. **This project therefore represents one step towards the creation of the information base to support these strategies.**

1.3 General concepts

1.3.1 Types of Account

Stock and change accounts for land cover and land use

For a given region or country there is a finite stock of land[15], the characteristics of which are determined by physical and ecological factors such as relief, geology, climate, vegetation and soils, together with a range of cultural and economic factors associated with the human use of those areas. However, the character of the land resource is not fixed, for with long-term environment change, and changing patterns of human development, the character of the land resource can be transformed over time. ***Stock accounts*** are one way of describing what types of land resources exist, and what kinds of changes occur over time.

In order to understand some of the key the issues underlying the construction of stock accounts for land, it is important to make a distinction between ***land cover,*** which is a description of the physical or ecological state of a given parcel of land, and ***land use,*** which is determined more by the human activities that the land supports, or its wider cultural or historic value. The distinction is important to make, for it is clear that in describing land resources, there is no simple relationship between cover and use. Thus a single cover type, such as woodland, may have a number of uses. In one area, for example that woodland may have an economic use though forestry. In another, it may have a recreational use. Conversely, a particular type of land use many involve many different cover types. 'Agriculture', is for example, a specific type of land use that may include a range of different cover types. The complexity of the relationship between land cover and land use is increased further in those situations where a single cover type can have **multiple** uses. The analysis of **multifunctional land use** or **landscapes, and the compatibility and conflicts between different types of land uses,** has emerged as an important issue within the EU, and it is one that can clearly be addressed by the development of land accounting techniques.

Various schemes have been devised to classify different types of land cover and land use. We may therefore exploit and use them to construct a set of related land cover and use accounts,

14 The Sixth Environment Action Programme - COM(2001)31

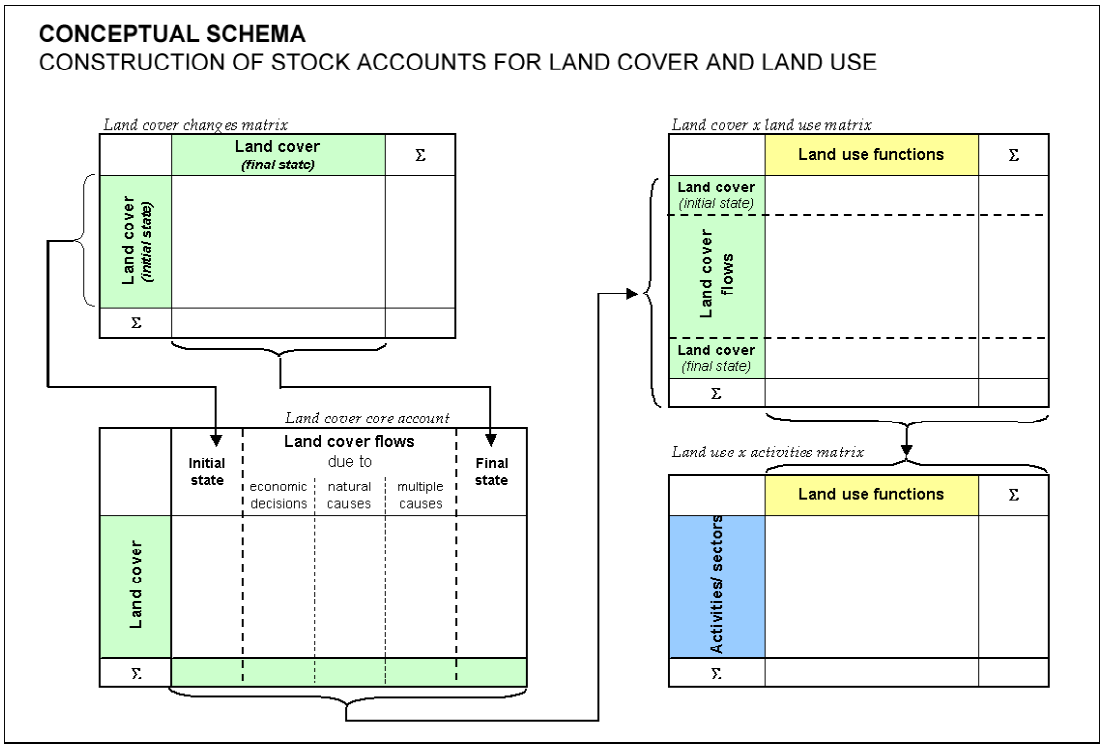
15 Locally or other long periods of time, this is not absolutely true and the LEAC will have to reflect these changes. Exceptions are of limited natural phenomena such as consequences of volcanic and seismic events. Coastal erosion and progradation or the creation of polders, some harbour or airport infrastructure or marinas reduce or expand land available for human use.

which ultimately map out how they change over time. A particularly valuable hierarchical classification scheme for land cover is the one devised for CORINE, which was developed as a result of the EU's need to provide up to date information on land cover at scale 1:100.000 for the whole Europe. The classification scheme at its more detailed level includes 44 categories of land cover based on a standard European nomenclature (level 3). These can be aggregated into 15, more general groups at level 2, or just five large groups at level 1, namely artificial surfaces, agricultural areas, forest and semi-natural areas, wetlands, water bodies.

In respect of land use, other classification schemes exist, including the Standard Statistical Classification of land use published by the Economic Commission for Europe (ECE). Such classifications are often problematic in that they often mix cover and use categories, and as a result they are often difficult to apply. For this project, a purpose-built classification of use was constructed, the details of which will be given below.

A conceptual schema showing how stock and change accounts for land cover and use can be constructed land cover is shown on Figure 1.2. A matrix can, for example, be used to show how the stock of land in each cover category changes over time. Such a device is particularly useful, because it records the transfers between categories as well as the overall change a given stock category exhibits over the 'accounting period'. Traditionally, such a change matrix has been used to present data on cover change from the analysis of satellite imagery or field survey data. Key features to note about the matrix are that the diagonal shows the proportion of each stock category that is stable over the monitoring period, while the row and column totals show the total initial and final stocks for each category.

Figure 1.2 - Conceptual schema for the construction of stock accounts for land cover and land use



These transformations expressed in the change matrix can be presented more clearly by constructing the table shown in Figure 1.2. (down-left), which shows for each cover type the

opening and closing balance, and the magnitude of the gains and losses due to various natural and economic factors. Such a Table is known as a **flow account**[16].

In the Table the (+) and the (-) values are explicit for each land cover, so that the final stock will equal the initial stock plus the algebraic sum of the flows into and out of that category. The ability to classify and represent these different types of transformation is a particular advantage of this kind of table over the simple matrix approach shown in Figure 1.2. (up-left). In order to trace some of the implications of the changes in stock which are shown in a table like that on Figure 1.2 (down-left), a further matrix can be constructed, showing the multiple relationships between land cover and land use (Figure 1.2 up-right). Such a matrix is particularly useful, because it represents the first step in relating land cover and use change to the various economic activity areas that are often a key aspect of any long term-policy strategy. In the schema shown in Figure 1.2, the flow account has a particularly important role to play.

Figure 1.3 – Example of cover account derived from the UK Countryside Survey

Areas which are more than 75% built up were not covered by the survey.

16 Also known as a 'screen account' in traditional accounting practice

Figure 1.3 shows an example of a real account constructed using data from the UK's Countryside Survey. In this account, the flows or types of change are classified into such processes as 'woodland creation', 'agricultural intensification', and 'development'.

More generally, for the SEEA it has been accepted that the main flows that should be distinguished are “changes due to economic decisions”, “changes due to natural causes” and “changes due to multiple causes”. Similar approach has been applied in the PTL/LC study done for EEA[17] in 1999, where 7 main flows has been defined on CLC level 2 (see Figure 1.4).

Similar approach has been applied here, too, but in case of this study for the 4 CEE countries, it was implemented by classifying the flows represented by the 15x44 CLC (level2/level 3) land cover change matrix. The classification of flows used was based on a compromise between the types of information required to make an informed environmental assessment and what can be extracted most reliably from CLC data. When the flows are broken down by land cover class, they can have either a negative or positive value. In the first case, the flow is regarded as a *consumption of land cover* (or simply of cover), resulting from the given flow. In the second case, the flow is a *formation of land cover* (of cover). For each flow, the magnitude of the 'consumptions' and 'formations' of cover are equal. The detail of the method and classification used will be described later in Part 3 of this report.

Basic and Supplementary Accounts

The flow account described above represents what can be though of a 'basic account'. In the original UNECE and EUROSTAT work that led to development of the accounting concept, a distinction was made between such accounts and those constructed for more specific purposes, say, to describe a particular theme or issue. These accounts are known as

[17] PTL/LC (1999) - Inventory and Analysis of Major Land Cover Changes in Central and Eastern Europe over the Past 20 Years, Topic Report, EEA Phare Topic Link on Land Cover (PTL/LC), GISAT

'supplementary' or 'targeted' accounts. In many cases such accounts are derived from these basic types of account, and present a more detailed view of the data.

One such type of such accounts are those used to give a **geographical** or **zonal** breakdown of the data. These accounts are particularly useful in the context of land cover and land use policy, because they allow us to see what geographical contrasts and differences occur between different regions and environments. More importantly they can show how a global indicator is expressed spatially. Ideally, the zonal breakdowns used should be specific to the phenomenon under study. However, when we examine cross cutting issues and/or interactions, it is useful to find some commonalities, including some common geographical pattern.

In fact, pre-existing units such as administrative units, river basins or other types of geographical breakdowns can be used. A classification of potential Land Analytical and Reporting Units (LARU's) is shown on Figure 1.5. Other approaches that are available include analysing the territory with a regular grid to which are associated attributes related to physical geography, vegetation and ecosystems and by human activities. Multi-criteria analysis can be used, to define a set of zones according to the combination of a specific set of characteristics (Figure 1.6).

Table 1.5 - Nomenclature for Land Analytical and Reporting Units

A - Analytical Units

- *Administrative Units*
- *Geographic Regions*
- *Geo-physical regions (River basins (small), Mountains areas (small…)*
- *Ecological regions (e.g. DMEER, Potential vegetation…)*
- *Other*
- *Land Analytical Units*
- *Geometric Units*
- *Grids*
- *Buffers*

B - Reporting Units

- *Administrative Regions, Countries*
- *Geographic Regions (e.g. River basins (large), Sea catchments, Mountain areas…)*
- *Bio-Geographic zones*
- *Geographic Sectors (grouping of LAU or Geometric Units according to proximity or to Landscape Types)*

Other types of targeted or supplementary accounts include those which seek to place a monetary or relative value on the resources or types of change within the flow account. Such accounts many for example, provide an important opportunity for the future in terms of showing how the value of various ecosystem goods and services are affected by different types of lands cover change. Targeted accounts derived from the basic data flow data can also be used to construct various other economic, social and environmental indicators, by linking the flow data to information about demographic change or ecological characteristics of the land cover units, such as biodiversity.

In this study the supplementary account based on a geographical breakdown of the data are present. The zonal units used to give this geographical breakdown are described below. Ultimately the aim is to develop such accounts to give a more detailed view of the important changes occurring in the study area by the creation of an additional set of targeted accounts for themes such as forestry. A provisional accounts for forestry is presented in this study. An overview of the relationship between the different types of basic and supplementary accounts is shown in Figure 1.7.

Part 2: Data Resources

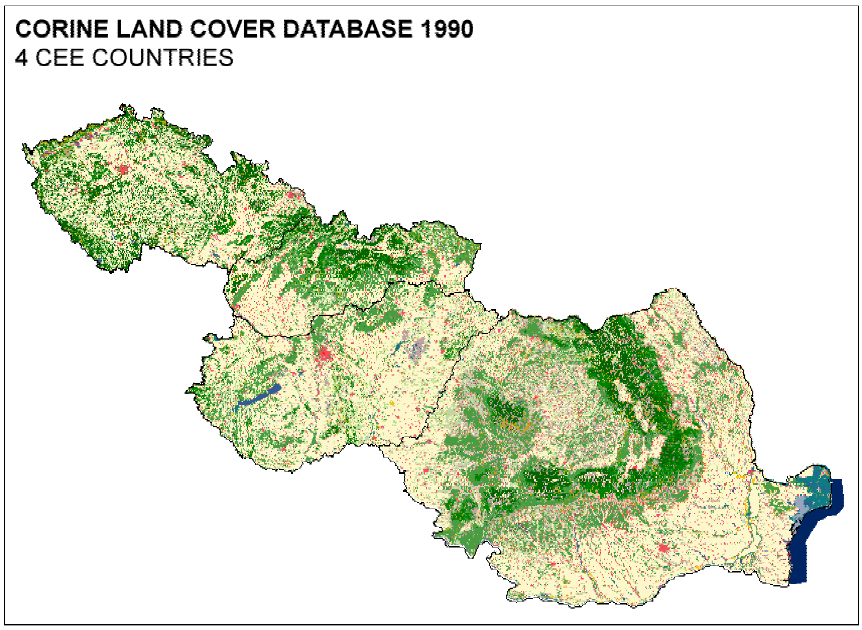
2.1 CORINE Land Cover database (1990, and potential 2000)

The CORINE Land Cover (CLC) database is a European-wide seamless geographic database on land cover / land use prepared according to uniform methodology during 1980s-90s. It provides consistent land cover mapping at a scale of 1:100 000, with a minimum mapping unit of 25 ha. Nomenclature includes 44 classes organised in three hierarchical levels. More general representations of CLC data can be given using the 15 classes in aggregation at level 2 or 7 classes at level 1. A detailed list of the classes of the nomenclature is included in Annex.

The CORINE Land Cover specifications have been defined in the first CLC Technical Guide[18]. The unique methodology covers both the basic interpretation principles and the particular methodology steps and consists of computer-assisted visual photo-interpretation of satellite images (mainly Landsat TM imagery), with the simultaneous consultation of ancillary data, classifying data into classes of the CORINE Land Cover nomenclature.

This data set encompasses most of the countries of the European Community[19], all 15 Member States of the European Union (except Sweden), as well as 13 Central and Eastern European[20] countries (Albania, Bosna-Hercegovina, Bulgaria, Czech Republic, Estonia, Hungary, Latvia, Lithuania, F.Y.R. of Macedonia, Poland, Romania, Slovakia and Slovenia). See example for the area of the study shown on Figure 2.1.

Figure 2.1 – Extract of CORINE Land Cover 1990 database for the 4 CEE countries



18 Y. Heymann, et al., CLC Technical Guide (1994)

19 http://dataservice.eea.eu.int/dataservice/other/land_cover/lcsource.asp

20 http://ptl.gisat.cz/clc_dirb1.shtml

The CLC database is being updated every 10 years. Recently, the ongoing I&CLC2000[21] project will provide a snapshot of land cover/use for the year 2000 by updating of the original database[22]. For the purposes of mapping change, a minimum changes unit of 5 ha is used.

Due to the comparability of data on European level the CLC database offers an excellent input for the European-wide land cover change studies. Nevertheless, certain limitation can be imposed by thresholds used for CLC mapping (25ha minimum mapped unit, 5ha minimal mapped change) in form of underestimation (or overestimation) of certain processes running on scale close to these thresholds. As example, a comparative study carried out on the French coast with aerial photographs at the scale of 1:25 000, shows the importance of a very diffuse urban sprawl, which is poorly detected by the satellite images in the CLC-like mapping before it reaches the minimum size of 25 ha (underestimation of change). In fact, this sprawl is identified at a later stage of the process, in a following period, when the process finally reaches the minimal mapped area (overestimation of change). This limited sensitivity of CLC suggests that phenomenon such as urban sprawl should be, in addition to CLC, monitored also at a larger scale with high resolution satellites or aerial photos and with a periodicity of 3 to 5 years maximum.

2.2 CORINE Land Cover database (1975)

In the frame of EEA Phare Topic Link on Land Cover (PTL/LC) the project of landscape changes identification and analysis was realised in 1998-1999[23]. It introduces the practical case of the large-scale application of the CLC database and the methodology of landscape changes inventory (a territory of the Czech Republic, Hungary, Romania and Slovakia) with the total area of almost half million km2 mapped). First phase of this project consisted of CLC database creation reflecting situation in the 70's by retrospective updating (downdating) of original CLC 1990 database.

From the methodological point of view this land cover database (CLC1975) was created by the computer aided visual interpretation of land cover changes as identified on archive satellite images (Landsat MSS imagery). In fact, the methodological approach was very similar to the one used in the I&CLC2000 project as the same threshold for change polygon was used (5 ha). Nevertheless, reflecting interpretability of Landsat MSS for mapping the land cover change, aggregation of the 3rd level classes to the 2nd hierarchic level of the CLC nomenclature was applied for CLC1975, which reduced the number of land cover classes 15. Other characteristics of CLC database remained intact (criterion of the minimum area 25 hectares and the minimum width 100 metres).

CORINE Land Cover 1975 database is available for the Czech Republic, Hungary, Romania and Slovakia.

2.3 Elevation data (Digital Elevation Model)

The digital elevation model (DEM) used in this project is the one from the GISCO database[24]. The resolution of this dataset is very coarse but is, nevertheless, sufficient for the purpose of mapping altitude throughout Europe, and for producing maps of major landscape types. For the purposes of this project, the combined elevation/slope threshold has been used for splitting the lowland, upland and mountain areas (see Figure 3.15).

2.4 Administrative boundaries

Administrative boundaries used in this project also came from the GISCO database. At this stage, only countries and NUTS3 have been available. For further integration of forest statistics in the Czech Republic case study other local level administrative boundaries required were obtained from national sources, as there are presently problems with access and dissemination of NUTS5 Europe-wide administrative boundaries.

2.5 Physical boundaries

The major physical units used as the basis for this study were drawn from the Biogeographic Regions and Watersheds contained in the GISCO database. The 'Regional Seas Basins' layer was obtained as aggregation of watersheds.

2.6 Statistical information

Socio-economic statistics have been used in this study for the forest case in the Czech Republic secured from various national sources, mainly form the Czech Statistical Office (CSO)[25] and the Forest Management Institute (FMI)[26]. More details on statistical data used can be found in Part 4.

Part 3: Basic Accounts

First, the accounting concept described schematicaly in Part 1 was implemented on level of the basic accounts for the 4 CEE countries. Following the developments of the "coastal part"[27] of the study, several additional issues were considered and further developed specific for this part of the study: adjustment of methodology and accounts for different classification of input land cover data, subsequent adjustment of classification of land cover flows and further refining of landscape types by introduction of broader altitute/slope characteristics needed for continental wide accounting. Details of methods and approaches used are described in this chapter.

3.1 General concept implementation

3.1.1 Main tables of the basic land accounts

Based on the general concept outlined above set of the basic account tables have been selected for presentation of land cover changes.

Matrix of land cover changes

This square matrix describes for each land cover type the changes between an initial situation (initial stock of land cover) and a final situation. When no change happens, the values are recorded in the diagonal. The difference between the final and the initial situation is the Net Change of land cover. The detail of the matrix depends on the database and on the information that is requested. Three complementary options are proposed, using CLC database: 1. a detailed matrix based on CLC level 3 (44 classes), 2. a semi-detailed matrix based on CLC level 2 (15 classes) and 3. an aggregated matrix based on CLC level 1 supplemented by some details (7 classes) as shown on Figure 3.1. In this study, working with CLC data for initial stock on level 2 only (15 classess), options 2. and 3. were applicable on initial part of this matrix as well as in case of other account tables.

Table 3.1 CORINE Land Cover Aggregated Nomenclature (Level 1 bis)

1	*Artificial surfaces*
2.1+2.2	*Arable Land & Permanent Crops*
2.3+2.4	*Pastures & Heterogeneous agricultural areas*
3.1	*Forests*
3.2+3.2	*Shrub and other semi-natural land*
4	*Wetlands*
5	*Water bodies*

27 Weber, J. L., Paramo, F., Breton, F. Haines-Young, R. (2003): Integration of geographical and statistical data in the environmental accounting framework; methodological development based on two case studies Action 2: Integration of environmental accounts in coastal zones; case study of tourism, Barcelona 2003, Contract n° 200141200017, EUROSTAT

Account of Land Cover Changes

This account is compiled by countries, regions or by landscape types. For one given land cover class, the changes are summarized in (+) and (-) values. Therefore, the final stock is defined as:

EQUATION *Initial stock + algebraic sum of Changes = Final stock*

Account of Formation of Land Cover

This account presents, by countries, regions or by landscape types, the balance between the *Formation of land cover* which has lead to the present situation and the *Consumption of land cover* from the past situation. The flows of Formation of cover and Consumption of cover are detailed according to the nomenclature of land cover flows (see the aggregated level of the Nomenclature of the Land Cover Flows used in this study on Figure 3.2). Assignment of individual land cover changes to these flows are discussed further in this chapter. In this account, each individual flow of consumption is balanced by a flow of formation of cover. For each Land cover class, the difference between Formation and Consumption is called "Net formation of cover". It can be positive or negative. The equation of the account is:

EQUATION *Formation - Consumption = Net Formation of land cover.*

When the stocks of land cover are introduced, the equation is:

EQUATION *Initial stock + Formation =Consumption + Final stock*
or
Initial stock + Net Formation of land cover= Final stock

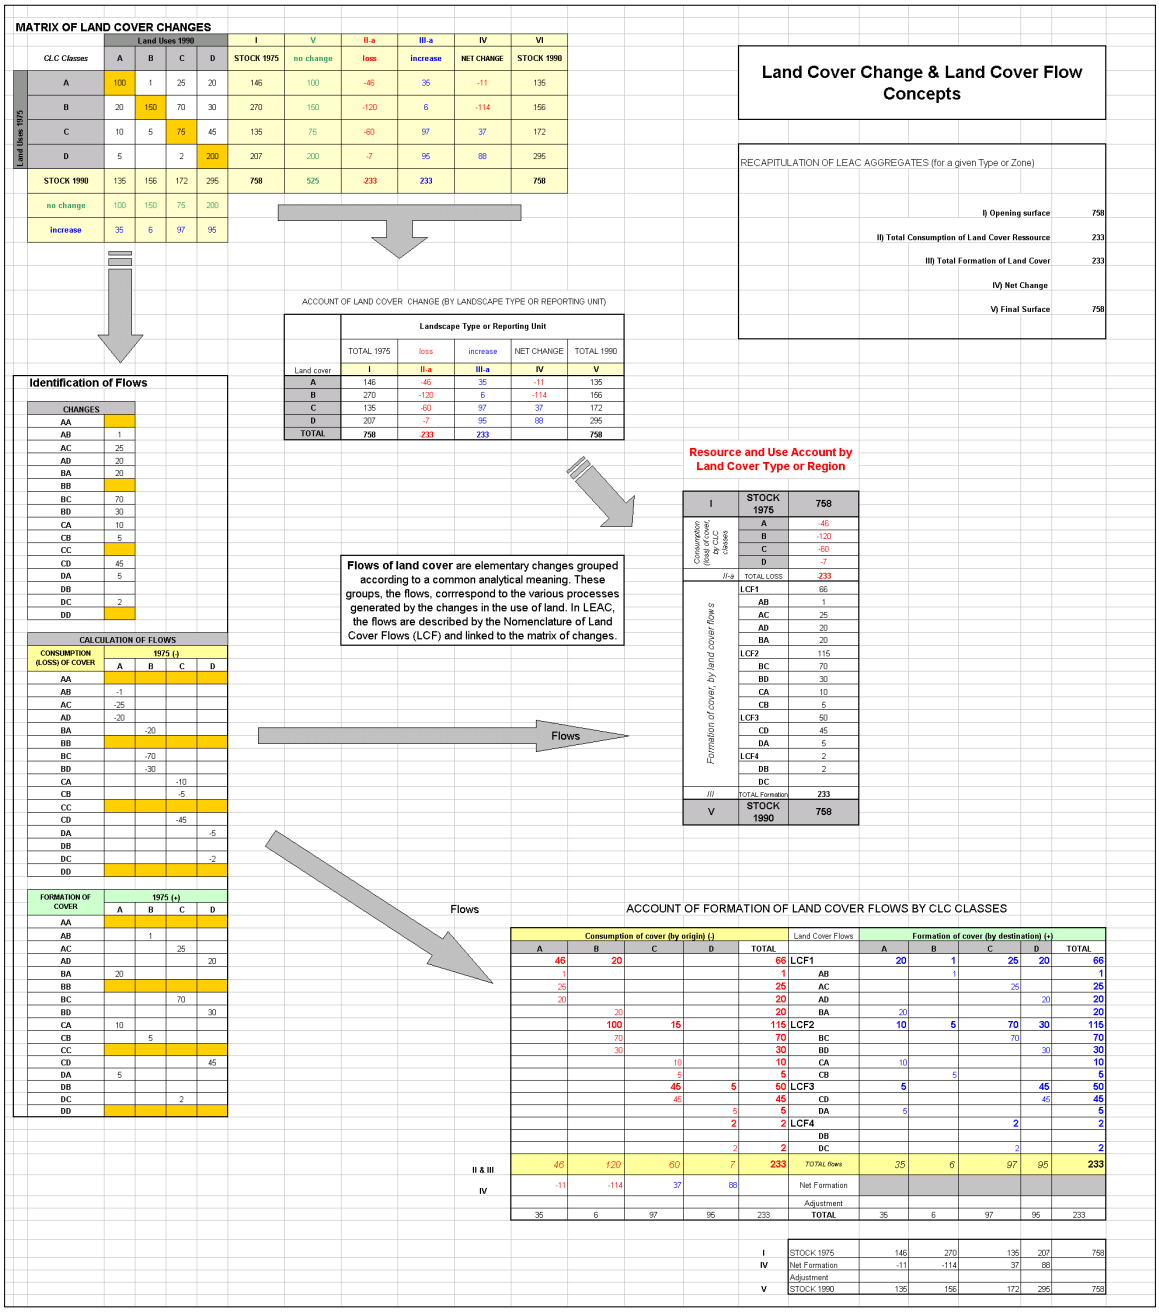
Table 3.2: Nomenclature of Land Cover Flows used (Level 1)

LCF1	*Urban land management*
LCF2	*Urban sprawl*
LCF3	*Extension of economic sites and infrastructures*
LCF4	*Agricultural rotation and intensification*
LCF5	*Conversion of land to agriculture*
LCF6	*Forests creation and management*
LCF7	*Water body creation and management*
LCF8	*Changes of land cover due to natural and multiple causes*

Accounting separately for the consumption and the formation has the advantage of presenting a total of flows which is identical, whatever the level of aggregation of land cover classes. This is different from the conventional matrixes of land cover change in which the aggregation leads to the consolidation of changes.

The balance of the Formation of Land Cover Account, i.e. the Net Formation of Cover is computed from flows when Net Changes are computed from the Matrix of changes as the difference of two stocks. At the most detailed level, the two results are strictly equal. When

Figure 3.3: Land Cover Change & Land Cover Flow Concepts



the two are compiled with an aggregated Nomenclature, an additional element has to be introduced to reflect the fact that the total of Formation or Consumption remains identical when the Changes vary due to the aggregation that "hides" internal flows in the diagonal of the matrix. These "hidden changes" have to be added to the result of the comparison of the two stocks. The equation is therefore:

EQUATION *Final Stock of cover - Initial Stock of cover= Net Change (at a given scale)*
= Net formation of cover -"hidden changes"(at a given scale)

The Formation of Cover Account can usefully be compiled by zones, region or landscape type.

Land cover Resource and Use account

This account aims at presenting a synthesis of stocks, changes (losses by Land Cover Classes) and Formation of cover by zones, regions or by landscape types, as the previous one. This presentation avoids redundancies (i.e. Formation and Consumption accounted with the same value, once + and once). The equation of the account is:

EQUATION *Initial stock – Loss of land cover (by CLC class) + Formation of land cover (by flows type) = Final stock*

In most cases, the initial and final stocks are equal equal, but theoreticaly they may differ in the cases mentioned in 1.3.1 footnote 10.

The full set of land cover change and land cover flows as well as the relation between the basic accounts proposed is summarized in Figure 3.3 using hypothetical numbers.

3.1.2 Classification and Nomenclature

A key data resource for land cover information in this study was CORINE Land Cover (CLC) data. Three level hierarchical classification system of CLC data includes at its most detailed level (level 3) in total 44 classes. Aggregation to level 2 results in 15 classes, while 7 classes is available on level 1. List of classes on level 1 and level 2 is presented in Figure 3.4. Complete classification on level 3 is included for reference in Annex.

Figure 3.4 – CORINE Land Cover Nomenclature (level 1 and level 2 aggregation)

LEVEL 1		LEVEL 2	
1	ARTIFICIAL SURFACES	11	Urban fabric
		12	Industrial, commercial and transport units
		13	Mines, dump and construction sites
		14	Artificial non-agricultural vegetated areas
2	AGRICULTURAL AREAS	21	Arable Land
		22	Permanent Crops
		23	Pastures
		24	Heterogeneous agricultural areas
3	FORESTS AND SEMI-NATURAL AREAS	31	Forests
		32	Shrub and/or herbaceous vegetation associations
		33	Open spaces with little or no vegetation
4	WETLANDS	41	Inland wetlands
		42	Coastal wetlands
5	WATER BODIES	51	Inland waters
		52	Coastal waters

When CLC data are used for land cover change matrix creation, total of 1936 (44x44) class combinations exist at the most detailed level 3. In order to support interpretation of land cover changes, typology of land cover changes to smaller set of land cover change types is therefore advantageous. Althrough certain ambiguities existed, working version of typology of land cover transformations was prepared for "coastal case study" based on inputs from existing typology attempts[28] [29] [30] and systematic definition of the land cover flows (LCF) in terms of

For the case study in the 4 CEE countries, CLC data on level 3 of CLC classification have been available for 1990 year, while CLC data used as reference to the situation in 1975 exist on level 2 only. Therefore, first, the LCF definition had to be addapted to be applicable on level 2 and at the same time as much as possible consistent for use on both level 2 and level 3 of CLC data. More, a complete check up of the matrix of definition of land cover flows was done and several changes have been introduced based on discussions following the Action 2 March Report.

By definition, the LCF were originaly classified for level 3/level 3 land cover changes, but analysis showed that most of the flows allowed aggregation of CLC classes to level 2 on consumption side ("from" class) of land cover change. In oposite, aggregation of CLC classes to level 2 on formation side ("to" class) of the land cover change was not feasible without considerable modification in the LCF definition. Therefore, it have been decided that for the 4 CEEC study, the LCF definition based on level 2 / level 3 land cover change matrix was used, which was, with few exceptions, consistent with definition on level 3 /level 3. The full table of correspondances is present in Annex.

Few exceptions in consistency between level 2 and level 3 matrices include:

- 243>22_ move from LCF52 – "Intensive conversion of marginal land to agriculture" on level 3 to LCF42 – "Planting of vineyards, fruit and olive trees over arable &pastures" on level 2.

- 243>21_ move from LCF52 – "Intensive conversion of marginal land to agriculture" on level 3 to LCF45 – "Intensification of agriculture" on level 2

30 Countryside Survey of Great Britain, www.cs2000.org.uk

- 213>41_, 42_ & 521 (abandonment of rice fields) move from LCF82 – "Farmland abandonment without significant woodland creation" on level 3 to LCF89 – "Other changes and unknown" on level 2.

- 523>423 move from LCF89 - "Other changes and unknown" on level 3 to LCF86 – "Coastal erosion" on level 2

Beside the exceptions described above, also the extended diagonal has to be considered when using level 2/level 3 change matrix. Obviously, this effect is concentrated on flows of internal rotations, but it can represents a limitation, when these flows are matter of specific interest.

In order to access mentioned differences in terms of hectares and percentage of total flows, a comparison of the LCF figures has been produced using available CLC1990 and CLC2000 data[31] (both on level 3) for Netherlands. Figure 3.6 shows summary of the results obtained for level 2 and level 3 matrix based LCF definition. It proves that. except the LCF52 and the LCF62, the flows figures are almost identical, especially at aggregated level. Certainly, in absolute numbers, this can be depended on type of landscape, but still is interesting message for future planning of country or European wide retrospective CLC inventories[32].

Figure 3.6 – Comparison of the LCF figures produced using level 2 and level 3 matrix based definition

LAND COVER FLOWS DEFINITION COMPARISON
LEVEL2/LEVEL3 DEFINITION vs. LEVEL3/LEVEL3 DEFINITION

	LCF definition - Level 2/Level 3					LCF definition - Level 3/Level 3						
	0	1	2	3	TOTAL	0	1	2	3	TOTAL	+/-	%
LCF1 Urban land management	11870	0	0	0	11870	11870	67	0	0	11937	67	1%
LCF2 Urban sprawl	40860	0	0	0	40860	40860	0	0	0	40860	0	0%
LCF3 Extension of economic sites and infrastructures	44465	0	0	0	44465	44465	0	0	0	44465	0	0%
LCF4 Agricultural rotation and intensification	30032	0	46	0	30078	30032	0	0	0	30032	-46	0%
LCF5 Conversion of land to agriculture	1327	0	0	0	1327	1327	0	46	0	1373	46	3%
LCF6 Forests creation and management	9095	0	0	0	9095	9095	38	0	0	9133	38	0%
LCF7 Water body creation and management	3711	0	0	0	3711	3711	0	0	0	3711	0	0%
LCF8 Changes of land cover due to natural and multiple causes	28373	0	0	1409	29782	28373	287	0	1409	30070	287	1%
TOTAL (ha)	**169733**	**0**	**46**	**1409**	**171188**	**169733**	**392**	**46**	**1409**	**171580**	**392**	**0%**

Note: 0 – consistent definition , 1 – diagonal effect, 2 – LCF5 to LCF4 moves, 3 – moves within LCF8

Using aggregated CLC classification on level 2 extended with classes 213, 243 and forest classes 311, 312, 313 (Level 2bis) would allow to assess land cover flows (as defined in this study) completely. For detailed comparison see table present in Annex.

31 CLC2000 data for Netherlands has been produced under the I&CLC2000 project and provided by ETCTE.

32 Retrospective CLC inventories demand extensive ancillary information support for interpretation of old satellite data or aerial photos. This represents a serious limitation due to restricted availability and cost of such information. Aggregated CLC nomenclature (e.g. from level 3 to level 2) can help reducing this demand.

Additional main changes introduced to the original LCF definition not connected to CLC nomenclature included:

- extension of activities within the urban perimeter (in a broad sense artificial) were reclassified to LCF11 – "Urban devepment/infilling". It allows better separation of flows 'within artifical area' from flows 'to artificial areas'. The extension is now considered against agriculture and nature. In this sense, the development of any item, e.g. harbours, commercial areas etc. is made of two parts: rotation and extension.

- exceptional land cover changes (previously N.A.) were classified into LCF89 – "Other changes and unknown" flow .

- accordingly exceptional flows related to Glaciers and Intertidal flats were classified into the LCF similar to the other classes of their group

- LCF81 with LCF83 were merged and subsequently LCF8 were renumbered

Figure 3.7 shows extract of final list of land cover change flows definition. Full list is present in Annex as well as full table of correspondance of land cover changes and land cover flows on level 2/ level 3. Detailed nomenclature of land cover flows is listed on figure 3.8. Hierarchical structure allows aggregation for summary accounting purposes still keeping detail insight to undergoing flows.

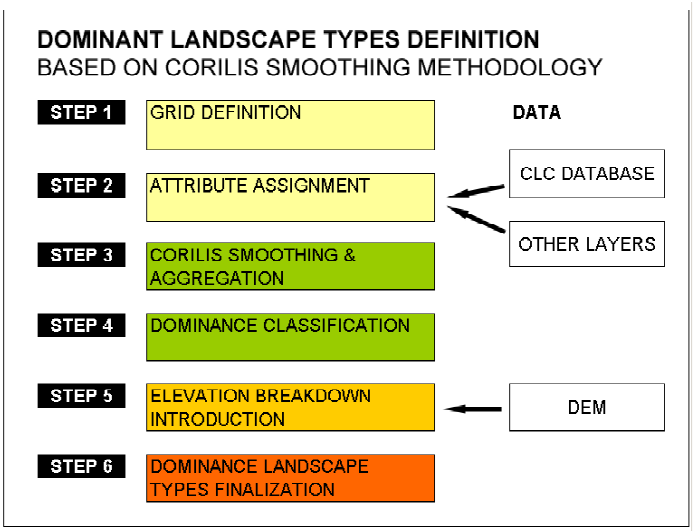
3.1.3 Definition of Land Accounting Units & Landscape types

Two general approaches can be followed for definition of land accounting units and landscape types. First one is based on landscape types definition by a statistical analysis of land units that are defined a priori. This means that it can be applied only if a distinct geographic pattern already exists, e.g. such as administrative units, river basins or climatic zones. Second one is based on analysis of the physical and the bio-physical (land cover) elements in a regular or iregular grid. As example, this solution has been used in the Countryside Survey of Great

Britain[33] for defining the Landscape types used later on for sampling in the field, as well as for reporting the results.

A similar approach has been chosen for creating LEAC, with the modification of in replacing the raw CLC data by smoothed data, using the CORILIS methodology (CORILIS = CORIne + LISsage – smoothing in French) at the European level. Using smoothed values creates a *de facto* zoning of the intensity (or potential) of a given land cover theme in one given cell and its surroundings. More about history and possibilities of CORILIS for a European-wide zoning can be found in the Action 2 Report from March 2003.[34]

Figure 3.9 – Dominant Landscape types creating based on CORILIS methodology



As a result, using the advantage of CORILIS methodology, maps can be produced showing spatial distribution of the intensity of an individual land cover type in an area . More, it is then possible to combine these paticular maps in a simple and transparent way in order to identify a dominant landscape type. This arrangement is flexible for modification, so the rules (as well as the parameters of the calculation) can be adjusted easily in order to achieve an acceptable representation for a given area. In this study CORINE land cover data were pre-processed using the CORILIS methodology and utilizing the software implementation developed by ETC-TE. Figure 3.9 gives an overview of application of CORILIS methodology for definition of Landscape Types in the 4 CEEC countries. In following paragraphs, it is further explained step by step.

Step 1 -Accounting grid definition

Spatial 'accounting grid' has been used for the 4 CEEC countries compatible with the one used for the Action 2. In fact, extract from this regular 3x3 km grid have been prepared covering the Czech Republic, Hungary, Slovakia and Romania. Usage of the accounting grid simplified resolving of slight spatial mis-adjustment between various data sources.

Step 2 -Attribute input to accounting grid

Additional attributes has been assigned to accounting grid by geographic intersection with other data sources as CLC1990 data, CLC1975 data, administrative boundaries etc.

---

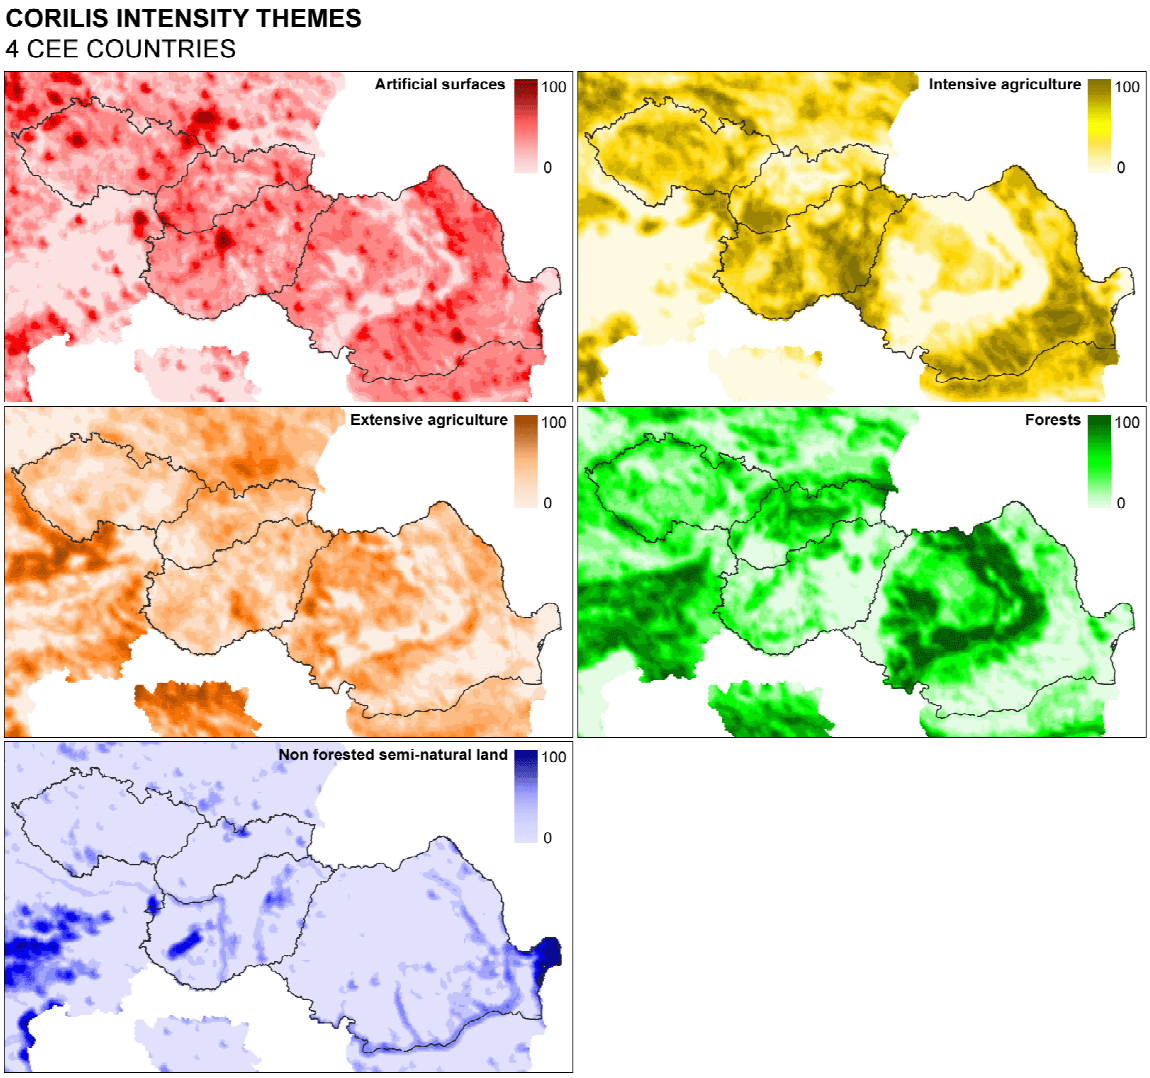
(2003): Integration of geographical and statistical data in the environmental accounting framework; methodological development based on two case studies. Action 2: Integration of environmental accounts in coastal zones; case study of tourism, Barcelona 2003, Contract n° 200141200017, EUROSTAT

Step 3 - CORILIS smoothing of CLC data – intensity themes creation

Geostatistical analysis of CLC data using CORILIS methodology has been performed in this step. CLC data (CLC1990) assigned to 3x3 km accounting grid were smoothed using a search radius of 20km and the Gausian function was used in smoothing algorithm to weight data in the neighbourhood of particular grid cell. Calculation were done on combined individual classes by simple addition of at aggregated level of the CLC data and 5 main themes have been produced: Artificial surfaces (1), Intensive agriculture (21+22), Extensive agriculture (or Heterogeneous agriculture & Pastures) (23+24), Forests (31) and Non forested semi natural land (32+4+5).

Figure 3.10 – CORILIS intensity themes for the 4 CEE countries



Each prepared theme represents percentage of area of a particular class within 20km radius. This way, aggregated intensity themes provide the information of the "intensity of neighbourhood" or "potential" of particular aggregated class.. Figure 3.10 previews five intensity themes created.

Step 4 - Classification to Dominant Landscape Types

In this step smoothed features – aggregated CORILIS classes were reclassified into the Dominant Landscape Types. The same nomenclature of main landscape types has been used as in "coastal study" as presented on Figure 3.11

Figure 3.11 – Nomenclature of main Landscape Types

A1	*Urban dense areas*
A2	*Dispersed urban areas*
B1	*Broad pattern intensive agriculture*
B2	*Composite rural landscape*
C1	*Forested landscape*
C2	*Open semi-natural or natural landscape*
C3	*Landscape with no dominant land cover character*

While A1, B1, C1 and C2 represent landscape types with clearly dominant landscape patterns, other three landscape types relate to dispersed or composite landscape patterns. A2 describes landscape where urban agglomerations are present, although in minority, but which are nevertheless significant in terms of their functions and probable future development. B2 corresponds to traditional European landscapes where mixed agriculture has historically coexisted with forests and other natural habitats. C3 is a type of landscape where no dominant land cover character has been identified, i.e. neither urban nor the agriculture or forest/natural ones determinant was detected. Such areas may be open to a particular type of future change.

Having defined main landscape types, a correspondence was established between the aggregated CORILIS classes and the Landscape types. Assignment was based on criterion that CORILIS dominance value Vn > mean + standard deviation (where Vn is the smoothed value of class "n" in particular grid cell). In order to introduce regional differences, mean and standard deviation values has been computed for each Sea Catchment separately. Nevertheless, in fact using this methodology often co-dominance of more classes can be present, therefore additional supplementary criterion had to be defined. The hierarchical "priority criterion" was based on the theoretical assumption as presented on Figure 3.12. The assignment of main landscape types has been done consistently with the previous part of the study and resulting Dominant Landscape Types are shown on Figure 3.13.

When compared the results, this methodology tends to slightly overweight the themes, when they are concentrated spatially. In particular, it was apparent for the urban areas (e.g. in area of high concentration of small urban areas in Carpathian region in Romania). Nevertheless, considering the fact that intensity of the environmental pressure by urban is usually (per hectare) much more important than by other classes (including intensive agriculture), this bias towards urban was found appropriate for the purposes of constructing LEAC. Modified criteria for dominance assignment as well as different thresholds have been tested, but finally the same criteria were used being compatible with coastal study and representing the best result for the 4 CEE countries.

Figure 3.12 – Correspondence between aggregated CLC land cover and main Landscape types

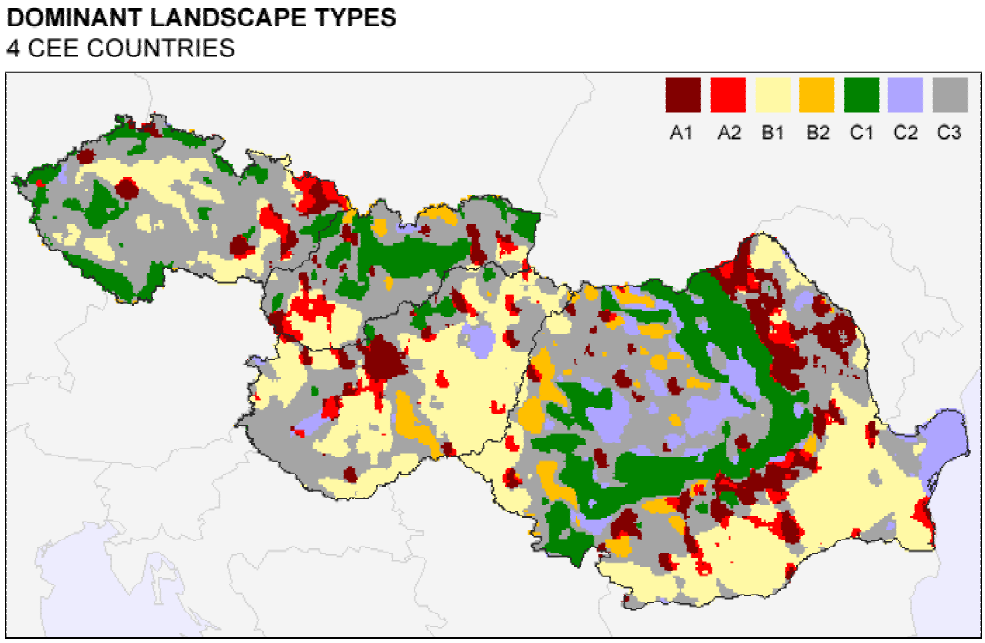
DOMINANT LANDSCAPE TYPE ASSIGNMENT
DOMINANCE CRITERIA

	A1	A2	B1	B2	C1	C2	C3
Artificial							
Intensive agriculture							
Heterogeneous agriculture & Pasture							
Forests							
Non forested semi natural land							

Dominant LC character of the type
Possible co-dominance, considered as secondary
No co-dominance is possible

A1 Urban dense areas	*Dominant urban character without any co-dominance*
A2 Dispersed urban areas	*Dominant urban character co-existing with agriculture, forests or semi-natural co-dominance*
B1 Broad pattern intensive agriculture	*Broad pattern intensive agriculture dominant character with no co-dominance*
B2 Composite rural landscape	*Dominant mixed agriculture and pasture with possible co-dominance of broad agriculture, forests or semi-natural land*
C1 Forested landscape	*Dominant forests character with possible co-dominance of broad pattern agriculture and semi-natural land*
C2 Open semi-natural or natural landscape	*Dominant shrubs and other semi natural and natural land with possible broad pattern agriculture co-dominance*
C3 Landscape with no dominant land cover character	*No dominant land cover characteristic identified*

Figure 3.13 – Dominant Landscape Types for 4 CEE countries



Step 5 -Introduction of elevation/slope breakdown

For the purpose of the 4 CEEC study, additional elevation breakdown has been introduced in addition to 200m altitude breakdown used for the "coastal study". The idea was to split "mountain areas" from "upland ones". The proposed threshold of 500 m for such split has been examined against policy documents and literature. As mountain municipalities are defined in EU regulations[35] by altitude (80% of the territory higher than 600m) and slope (various expressions), the threshold of 500 m alone would lead to classifying large plateaux dominated by broad pattern agriculture in "Mountain areas", which would not conform to the current definitions. Therefore, it has been decided to introduce a criterion of slope in order to

[35] e.g. "Severely Disadvantaged Areas" - land classed as LFA under Directive 75/268/EEC

keep large plateaux (or altitude plains) in "Upland areas". See final criterion definition on Figure 3.14. Despite "Mountain areas" are initiated there, classification is still consistent with the one used for the "coastal study".

A methodology was tested based on 1km GISCO DEM and the resulting elevation/slope breakdown layer for 4 CEE countries is present on Figure 3.15

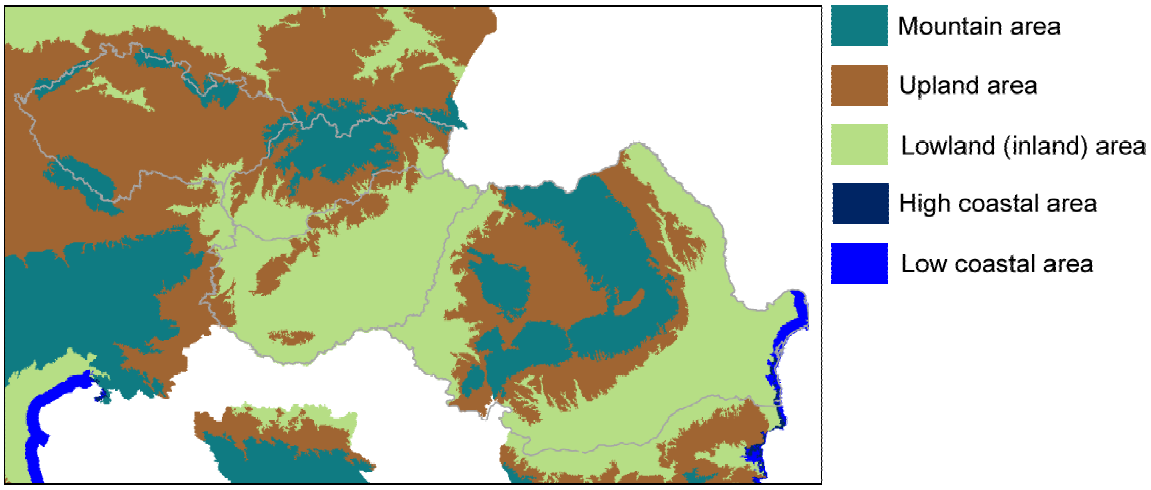
Figure 3.14 – Criterion definition for introduction of Mountain areas

ELEVATION/SLOPE BREAKDOWN CRITERIA

ELEVATION (m)	In the Coastal strip	Not in the Coastal Strip SLOPE (%) < 2	> 2
0 – 50	Low coast	Inlands	
50 – 200	High coast		
200 – 500		Uplands	
500 – 1000		Uplands	Mountain
> 1000		Mountain	

Figure 3.15 – Final elevation/slope breakdown layer

ELEVATION/SLOPE BREAKDOWN LAYER
4 CEE COUNTRIES



Step 6 - Final Dominant Landscape Types creation

Finaly, the elevation/slope breakdown have been added to original landscape types, namely to classes B1, B2, C1, C2 and C3 (see Figure 3.16). The introduction of the Mountain areas and the decision to assign the geographic rule also to the B1 Landscape type led to the presentation of the DLT nomenclature in 3 levels. The third level is *de facto* used for coastal zones only, but this arrangement allows to be compatible with classification for both coastal and European-wide studies. This classification should be used until 2004 when a revised version of CLC1990 will be available as well as a standard km grid for Europe. The final Dominat Landscape Type classification is listed on figure 3.18. and presented for the 4 CEE countries on Figure 3.17.

Figure 3.16 – Combination of original Dominant Landscape Types with breakdown layer

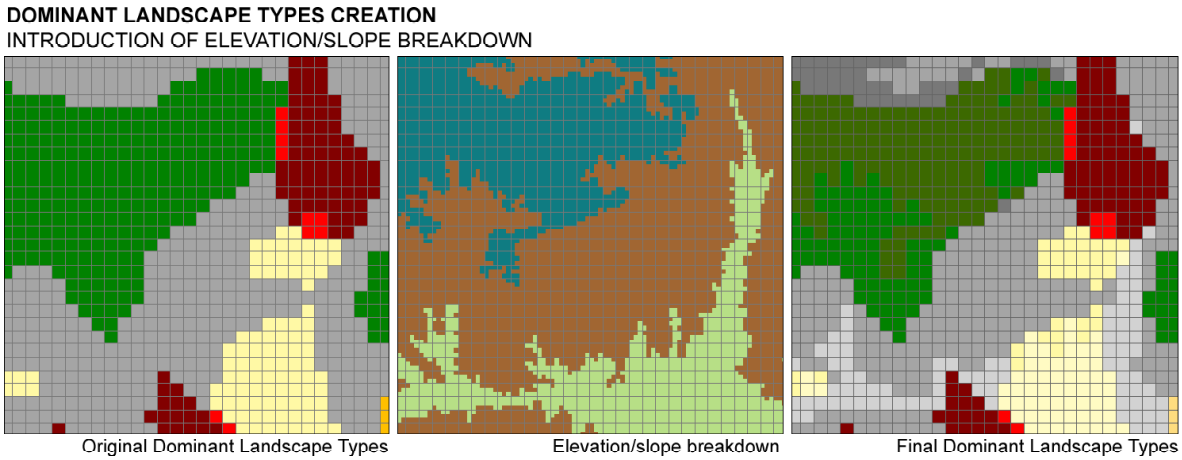


Figure 3.17 – Final Dominant Landscape Types for 4 CEE countries

B23 Mountain composite rural landscape

C1 Forested landscape

C11 Lowland forested landscape
C111 Low coastal forested landscape
C112 High coastal forested landscape
C113 Inland coastal forested landscape
C12 Upland forested landscape
C13 Mountain forested landscape

C2 Open semi-natural or natural landscape

C21 Lowland open semi-natural or natural landscape
C211 Low open semi-natural or natural landscape
C212 High open semi-natural or natural landscape
C213 Inland open semi-natural or natural landscape
C22 Upland open semi-natural or natural landscape
C23 Mountain open semi-natural or natural landscape

C3 Landscape with no dominant land cover character

C31 Lowland with no dominant land cover character
C311 Low landscape with no dominant land cover character
C312 High landscape with no dominant land cover character
C313 Inland landscape with no dominant land cover character
C32 Upland with no dominant land cover character
C33 Mountain with no dominant land cover character

3.2 Results

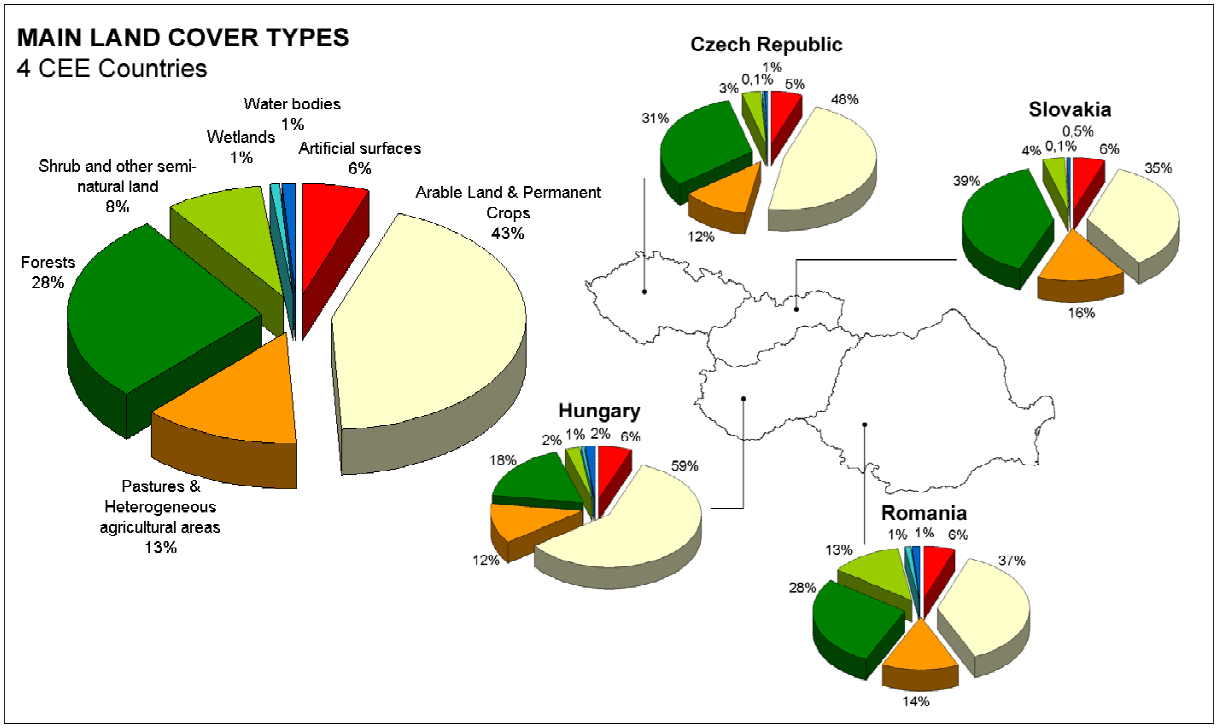
Using the above described classifications, nomenclatures and landscape types, full set of the basic accounts have been prepared according the general concept to test the feasibility of the basic accounts methodology on existing data. First, the basic accounts have been prepared on country level for the 4 Central and Eastern European countries. Later, more detailed spatial breakdown have been used for the basic accounts of the Czech Republic, which were used for the subsequent Targeted Accounts trial focused on forest and biodiversity.

3.2.1 Results for the 4 Central and Eastern European countries

The four Central and Eastern European countries covered in the study, Czech Republic, Hungary, Slovakia and Romania, represent countries with rather distinct landscape patterns, ideal for assessment of methodology application in areas with different landscape dominances.

On one side Hungary, country with predominant lowland landscape suitable for intensive agriculture, where only the northern part of the territory has gentle highland character. On the other, Romania and Slovakia, countries which include extensive mountain landscape of Carpathian mountain range with large areas of continuous forests and semi-natural land. More, in case of Romania, there are also large areas of wetlands present near the Danube river delta. Finally, somewhere in between, the Czech Republic with predominat heterogeneous, patchy and hilly landscape manifested by mixture of agricultural land, pastures and forests. These differences are reflected in distribution of main land cover types (as defined by CORINE Land Cover project, see figure 2.1 in Part 2) in each particular country presented on Figure 3.20.

Figure 3.20 – Distribution of the major land cover types in the 4 CEE countries



Full set of detailed basic accounts prepared for each country is included in Annex. Following paragraphs gives an overview of results and shows some interesting points apparent in produced accounts.

First, on Figure 3.21, the matrix of land cover change outlines the basic land cover changes which have occurred on aggregated level of main land cover classes in the 4 CEE countries during the study period 1975-1990. In total about 5 % of the total area have been subject of change leaded by changes in forests, shrub & semi-natural land and agricultural areas.

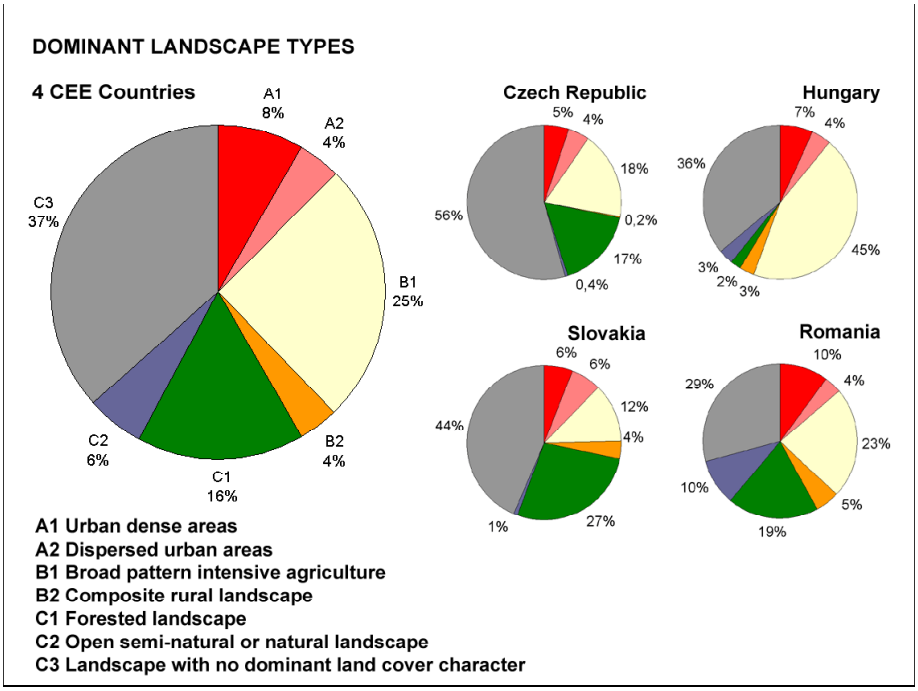
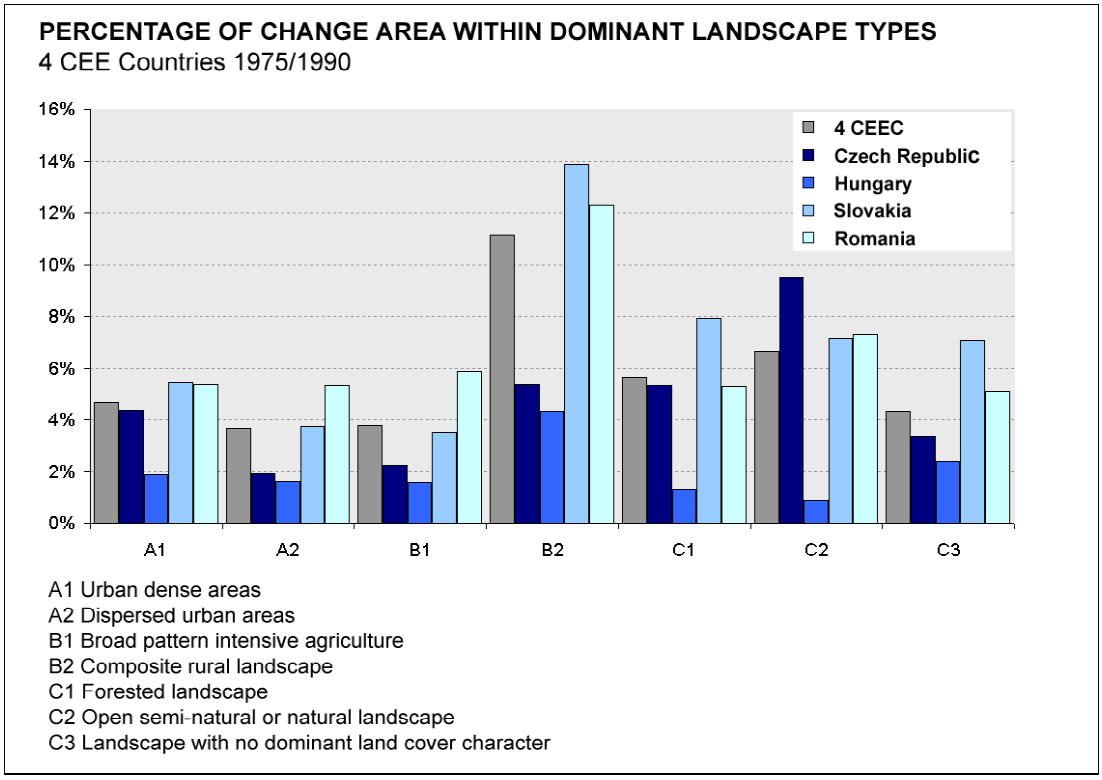
Figure 3.22 – Dominant Landscape Types for the 4 CEE countries



In addition to separate country accounts produced, further zonal breakdown have been applied using defined Dominat Landscape Types. Figure 3.22 on previous page shows the resulting proportion of area assigned to particular main landscape type. A first analysis proved that it correspond very well with distinct character of each country landscape as described above. Full classification of landscape types including also elevation aspect was used for detailed accounts listed in Annex.

Having the main landscape types assigned, we could compare percentage of changed area within particular landscape type (in % of total landscape type area). As seen on Figure 3.23, (in average!) the most "dynamic" areas are those belonging to "composite rural landscape" and "open semi-natural or natural landscape" followed by "forested landscape". Nevertheless, it is evident that differences between particular countries are high. In fact, on country level we get a completely different sequence of "dynamics" of main landscape types for each country.

Figure 3.23 – Percentage of change area per Dominant Landscape Types for the 4 CEE countries



Further details can be analysed when data are presented in the Summary Land Cover Change Account prepared per Landscape Types on Figure 3.24 as well as the Summary Account of Formation of Land Cover on Figure 3.25. In particular the Account of Formation of Land Cover presents the balance between Formation and Consumption. This account is established by CORINE Land Cover classes, their total being equal for each individual flow. The balance of the account is then the Net Formation of Land Cover. The Net Formation of Cover is at the same time the difference between the two stocks, Land Cover 1975 and Land Cover 1990.

Detailed versions of both accounts for each country are present in Annex.

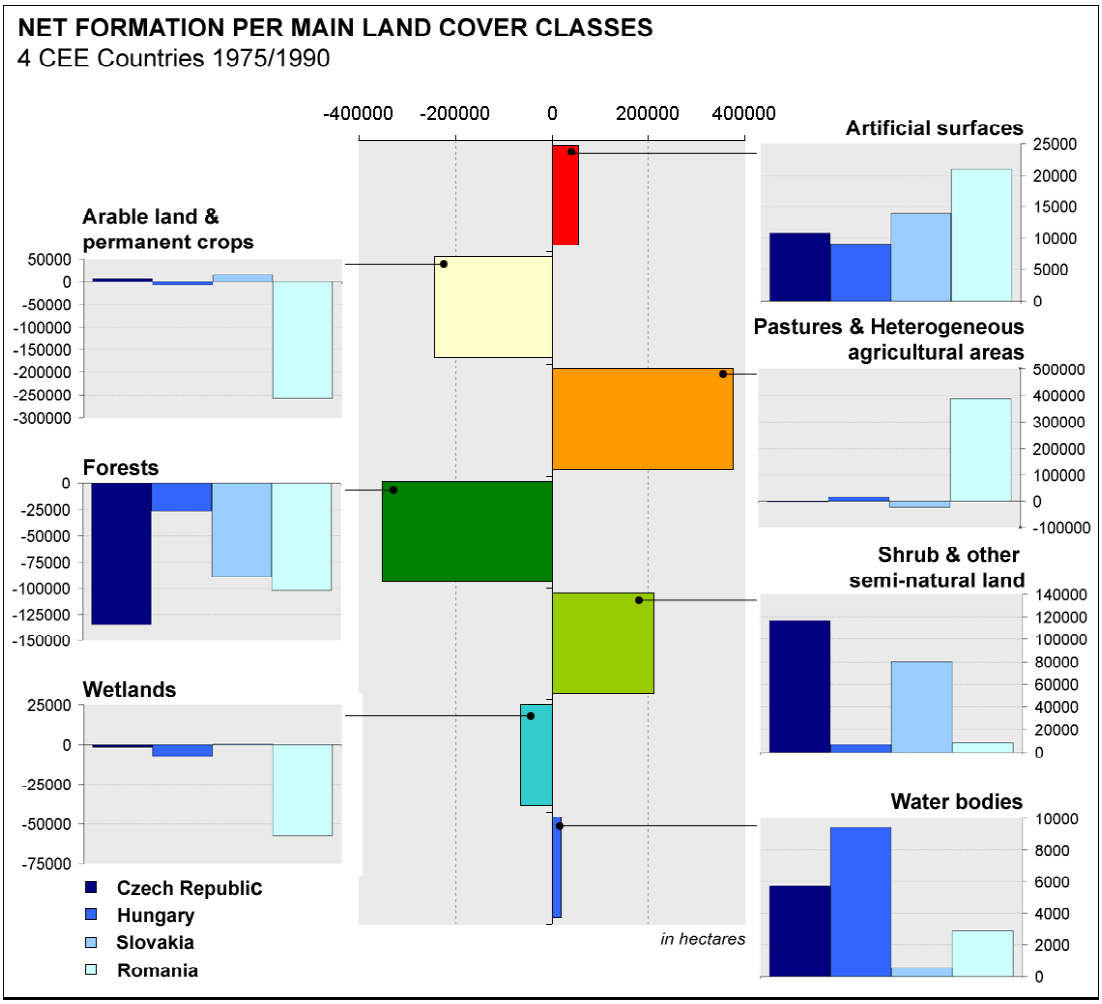
Figure 3.25 – Summary Account of Formation for the 4 CEE countries

Based on these accounts, a comparison of the particular Net Formation per each land cover type as identified for the Czech Republic, Hungary, Romania and the Slovak Republic is presented on Figure 3.26. It provides an integrated view on total net formation for the 4 CEE countries combined with country breakdown for each main land cover type. Although the same net formation trend can be noticed for most of land cover types (with exception of agricultural land cover types: arable land & permanent crops, pastures & heterogeneous agricultural areas), quite different intensity is manifested in particular country.

Figure 3.26 – Total Net Formation per major land cover types for the 4 CEE countries



To understand net formation figures presented above, we have to combine it in particular case with information about natural, social, economic and political consequences in respective period (which is in fact on of the aims of the Targeted Accounts). As example, exceptionaly high changes in agricultural areas in Romania have been connected with extensification of agriculture as a consequence of new law (the Land Use Act No.18) in the beginning of 90ties, when agriculture land returned to former owners was subsequently divided in parcels for complex cultivation with lesser share of arable land. In opposite, considerable decrease of area of wetlands in Danube delta area in Romania is caused by agriculture intensification supported by the government. The greatest share of changes in forested land is represented by decrease of forests and enlargement of transitional woodland-scrub due to air pollution in the Czech Republic.

More synthetic view of the land cover change data is provided also the Land Cover Resource & Use account by identifying both the processes of land cover change (that is the Formation of cover), as well as the losses, which are distributed by landscape type. Zonal breakdown per landscape types is shown on Figure 3.27, where selected interesting sub-flows are highlighted in blue. Detailed Land Cover Resource & Use accounts for each country are included in Annex, nevertheless several important points apparent from summary account are presented further.

Figure 3.27 – Land Cover Resource and Use account for the 4 CEE countries

SUMMARY LAND COVER RESOURCE AND USE ACCOUNT

4 CEE COUNTRIES 1975/1990, Surface by Landscape Types in hectares

Summary Account	Landscape Types							
	A1 Urban dense areas	A2 Dispersed urban areas	B1 Broad pattern intensive agriculture	B2 Composite rural landscape	C1 Forested landscape	C2 Open semi-natural or natural landscape	C3 Landscape with no dominant land cover character	TOTAL

C - TOTAL LAND COVER FLOWS 1975-1990	179250	70436	437740	188512	417438	175650	730132	2199158
D - Final Surface ~ 1990 (D = A-B+C)	3826767	1919825	11620390	1693580	7375943	2639629	16766525	45842658

For example, Figure 3.28 express the level of urban management flows as well as flows representing conversion of land into urban. Urban extension appears to be driven by extension of economic sites and infrastructure rather then urban sprawl. The data suggest that in terms of total area in hectares, urban expansion is highest in areas already dominated by dense urban, but also areas with specific no dominance contribute significantly. When the same figures analysed in relative terms of percentage of total area in particular landscape type, it is evident that expansion is more frequent process in those areas already dominated by urban (both dense and dispersed) then elsewhere.

Figure 3.28 – Urban related flows in the 4 CEE countries per Landscape Types

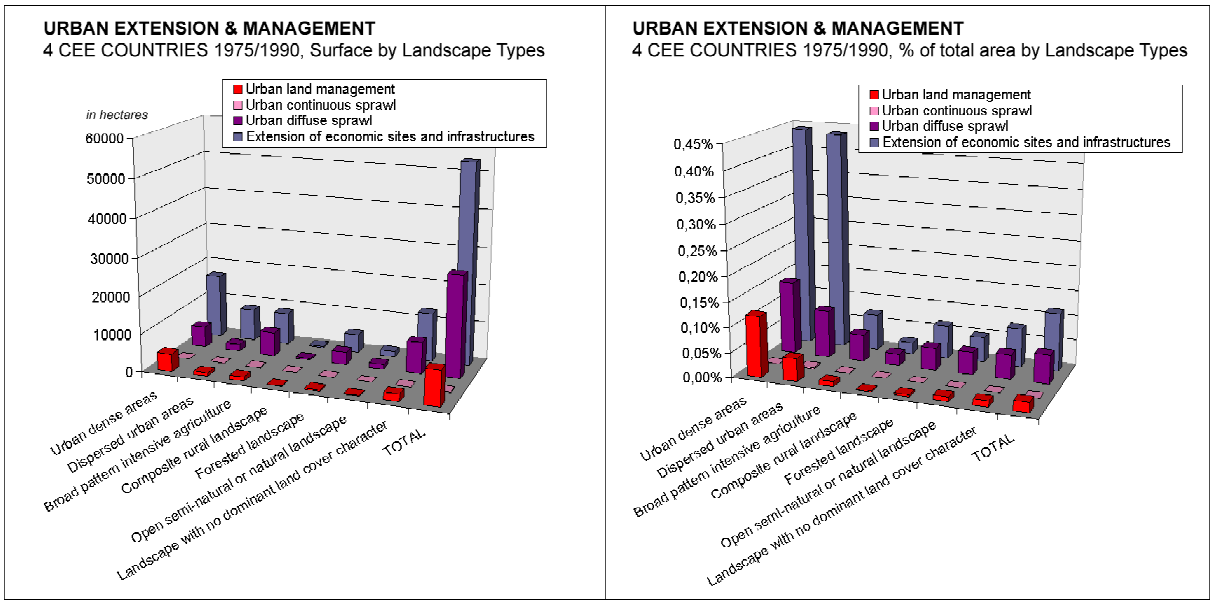

Figure 3.29 – Forest vs. agriculture flows in the 4 CEE countries per Landscape Types

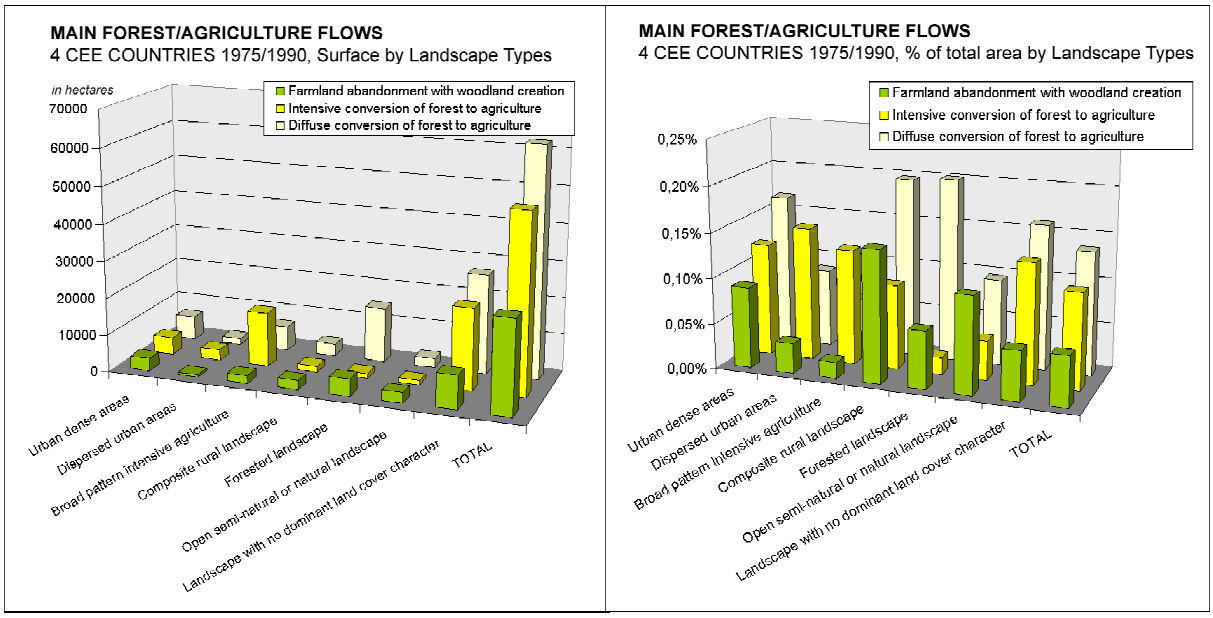

Similarly, we can identify exchange flows between agriculture and forest land. The data on Figure 3.29 suggest that, in terms of hectares, conversion of forest to agriculture far exceed the oposite flows, due to farmland abandonment accompanied with woodland creation, irrespectively of the landscape type. Further analysis in terms of relative values (percentage of total area per particular landscape type) prove this assumption, but uncovers high variability of such processes in individual lanscape type.

Figure 3.30 – Main forest in the 4 CEE countries per Landscape Types and elevation/slope zones.

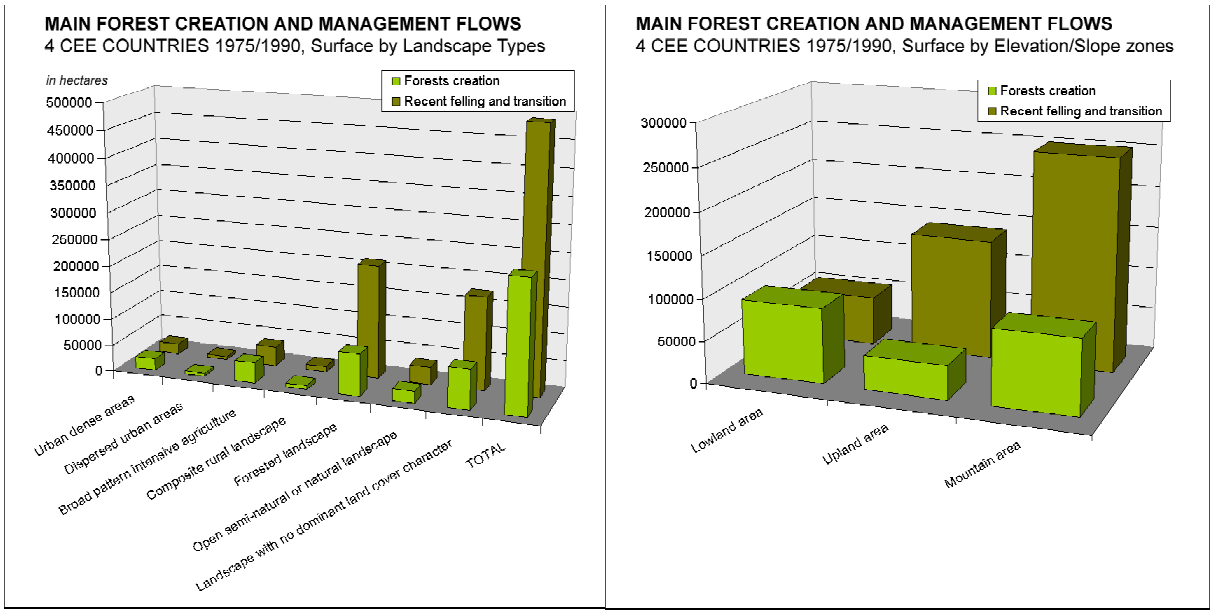

Figure 3.30 presents the analysis of main forest flows, forest creation and oposite recent felling and transition . The figure indicates the fact, that in average negative net formation of forests occurs, but on the other hand, it also demonstrate that in landscape types dominated by urban and agriculture these processes are more or less balanced. From this point of view the interesting result is obtained when using elevation/slope breakdown, where possitive net formation of forests is flashed in lowland areas. Please note that these figures exclude areas with urban dominance as currently now elevation breakdown was applied in these landscape types.

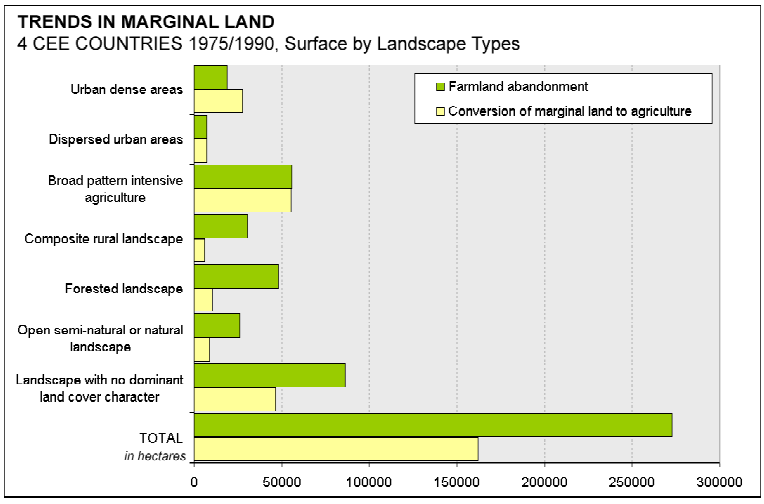
Figure 3.31 – Trends in marginal land in the 4 CEE countries per Landscape Types



Finaly, the figure 3.31 showing the trends in marginal land development in the 4 CEE countries has been produced for comparison with the same figure in the "coastal study". While generaly similar, it present a different pattern in case of agricultural areas (both broad pattern intensive agriculture and composite rural landscape) in favour of farmland abandonment. We suggest this as a first indication of processes connected to changes of land

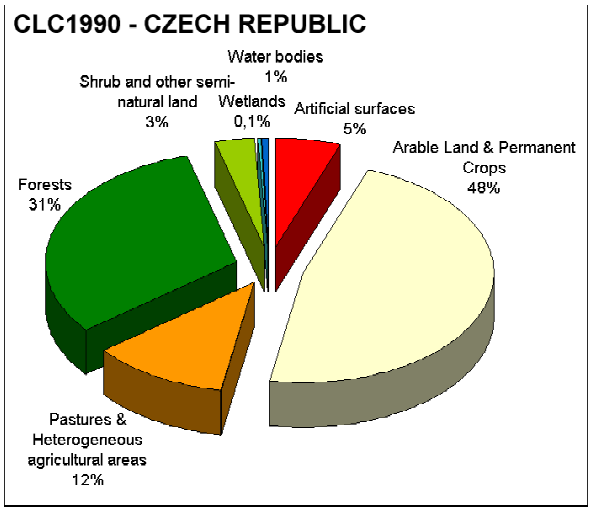
property ownership, which just started at during the last years of our study period (particularly in large extent in Romania).

All above presented figures are only preliminary results showing the avantage of land cover change information structured in the form of basic accounts as well as their spatial breakdown for assessment. These information will be subject of more detailed analysis in future, in particular in the context of additional information as well as using different spatial breakdown according zonal approach.

3.2.2 Results for the Czech Republic Regions

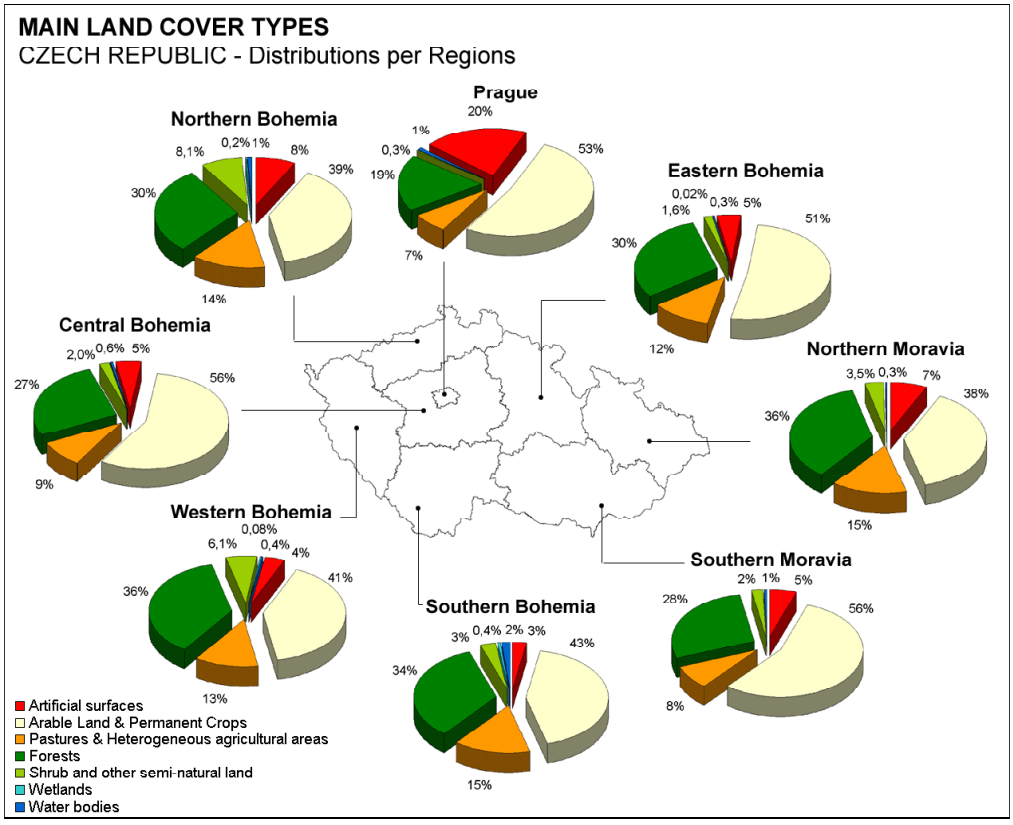
Considering availability of statistics about forest, finaly administrative regions have been selected as appropriate level of Land Reporting Units for preparation of Targeted Accounts (disscused detail in Part 4). Therefore, in addition to the basic accounts on country level and by Landscape Types, the basic accounts for 8 regions have been produced. Detailed accounts are presented in Annex. Following pages give these information in summary with some interesting points focused on forest land status and flows as present in the basic accounts.

Figure 3.32 – Main land cover types in the Czech Republic.



Figures 3.32 and 3.33 show the proportion of the major land cover types within the Czech Republic as well as its regional variation. As seen, the regional differences are not very high. Prevailing landscape is heterogeneous and with partial exception of traditional regions of agricultural production (e.g. Central Bohemia and South Moravia), no land cover type is clearly dominating. The forest areas occupy about one third of the total area of the depending on the appropriateness of land for agriculture. Large continuous forest areas are concentrated mainly in mountainous regions situated along the state border.

Figure 3.33 – Main land cover types distribution in particular region of the Czech Republic.



The summary matrix of the land cover changes recorder between 1975 and 1990, using the aggregated CLC cover classes, is shown on Figure 3.34. As seen, total change area during studied period represent about 3,5% from the total area of the Czech Republic.

Figure 3.34 – Land cover resource and use account for the Czech Republic by Regions

SUMMARY MATRIX OF LAND COVER CHANGE
CZECH REPUBLIC 1975/1990, Surface in hectares

FINAL YEAR ⇊ / OPENING YEAR ⇉		1 Artificial surfaces	2.1+2.2 Arable Land + Permanent Crops	2.3+2.4 Pastures + Heterogeneous agricultural areas	3.1 Forests	3.2+3.3 Shrub and other semi-natural land	4 Wetlands	5 Water bodies	TOTAL OPENING YEAR ~1975	Increase (+)	Decrease (-)	Net Changes 1975-1990	TOTAL FINAL YEAR ~1990

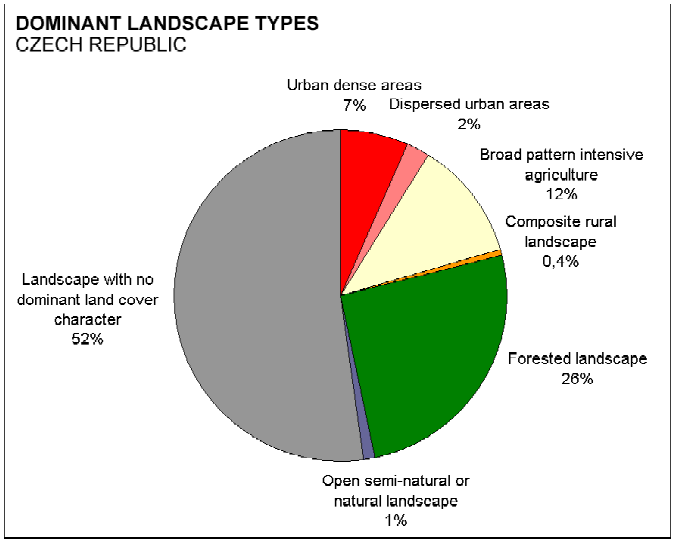
5	Water bodies	312	139	354	325	163	46	46320	47660	7063	1339	5723	53383
TOTAL FINAL YEAR 1990		429694	3724474	935851	2462655	274444	7516	53383	7888016	276233	276233		7888016

Total net changes are generaly small, except huge changes in “Forests” and “Shrub and other semi–natural areas” classes demonstrated in dramatic decrease of timberland area (31) in favour of class 32. Further analysis of the forest related changes can be done using Land Cover Change Account per Regions on Figure 3.36. Dramatic changes can be identified in Northwest Bohemia, in the area of strong concentration of mining, chemical industry and power supply resulting in excessive air pollution. Further, these changes appear also in Krkonose Mountains, which were affected also by the air pollution as well as military activities (military bases). The next important group of changes (more then 10% from total changed area) occurred due to intensification of agriculture or crop rotation practices.

Figure 3.35 – Land Cover Change Account of the Czech Republic per Regions



In terms of relative figures we should also note high decrease in percentage of total area of wetland during study period.

Analysing land cover changes by landscape types allows another perspective in understanding of the processes of land cover change. Figure 3.35 shows proportion of main Dominant Landscape Types in the Czech Republic. Large percentage of area with no clear dominance reflects well heterogeneous character of

majority of landscape in the Czech Republic. Summary Land Cover Change Account per Landscape Types is presented on Figure 3.37. Detailed Land Cover Change Account per Landscape Types (present in Annex) allows also further split and analysis of figures based on altitude.

Figure 3.36 – Land Cover Change Account of the Czech Republic per Regions

Another presentation providing better insight into land cover changes processes is the Account of Formation of Land Cover, which represents the balance between Formation and Consumption per individual defined flows (LCF). This account is established by CLC classes, their total being equal for each individual flow. The balance of the account is the Net Formation of Land Cover. The Net Formation of Cover is at the same time the difference between the two stocks, Land Cover 1975 and Land Cover 1990. Summary Account of Formation of Land Cover for the Czech Republic is shown on previous page on Figure 3.38. Using the detailed Account of Formation of Land Cover (present in Annex) we are able to trace in depth exact contribution to/from particular land cover class to individual defined flows and vice versa.

Finaly, the Land Cover Resource & Use Account provides a more synthetic view of the land cover change data, by identifying both the processes of land cover change (that is the Formation of cover), as well as the losses, which are distributed by Regions (Figure 3.39) or by Landscape types (Figure 3.40). Selected sub-flows related to agriculture, farmland abandonment, marginal land, forest and wetlands are highlighted in blue. Regional and zonal approach clearly show different profiles and facilitate a more detailed commentary on the statistics. Comprehensive assessment of presented figures is far beyond this study, but some of the interesting finding related specifically forest to flows apparent in produced accounts is further developed on Figures 3.41 – 3.46.

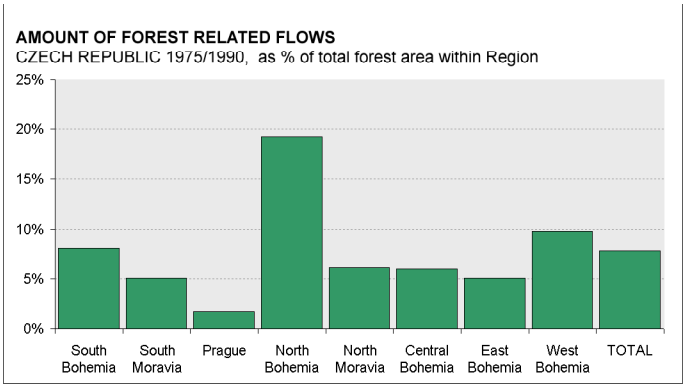
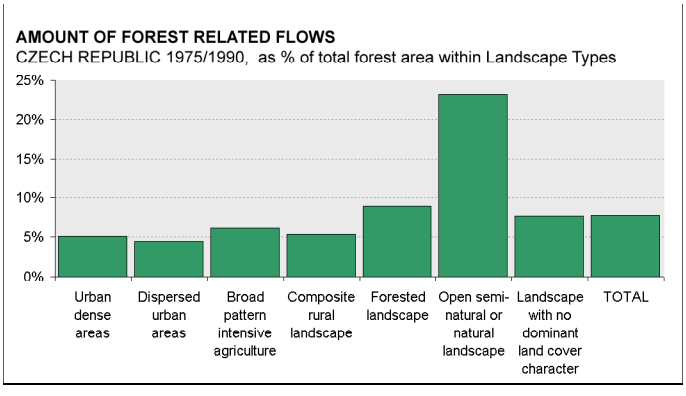
Figure 3.41 – Amount of forest related flows in the Czech Republic by Regions and Landscape Types



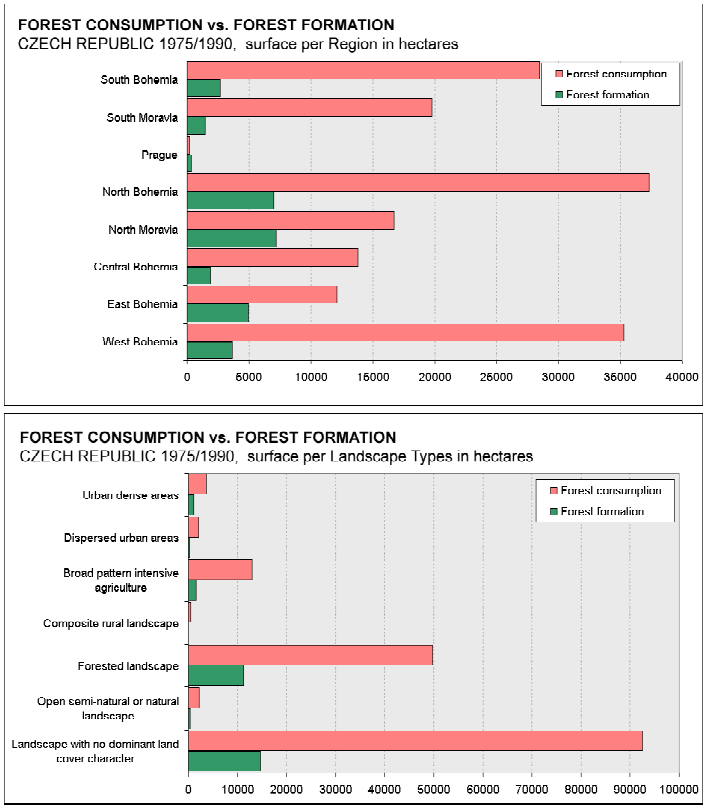


In average about 8% percent of the forest areas are subject of some change, percentage being extremely high in North and West of the country (~20%) as well as in Open semi-natural or natural landscape type (~24%). As explained above reason for massive changes was mainly excessive air emissions by coal-burning power plants especially in Mountains Krusne hory and Krkonose and these changes regard more to change of the forest quality and health than a total extent. Part of forest changes also belongs to a regular forest cut-grow process as large amount of wood was exported.

It also shows that the damaged forest was simultaneously restored, but not with the same intensity as damages

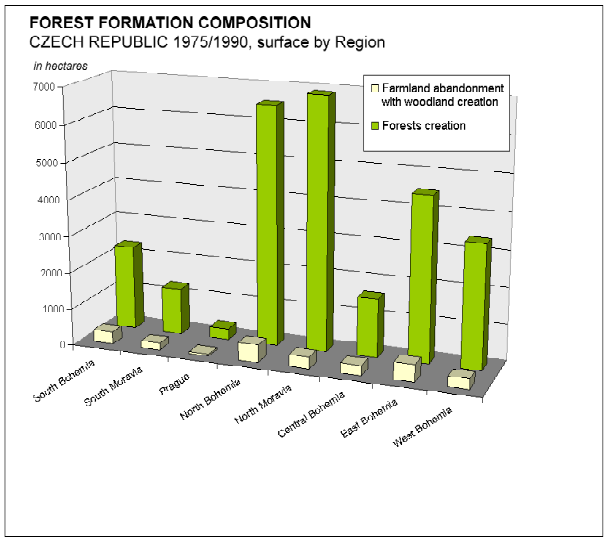
occured. Figure 3.42 presents regional overview on ratio between forest consumption and forest formation flows as well as it allows their perception per main Landscape Types.

Figure 3.42 – Consumption vs. formation of forest in the Czech Republic by Regions and main Landscape Types



Using the prepared basic accounts, we can have a closer look at composition of both the consumption and the formation flows. We can identify more detailed thematic breakdown of total flows according to particular sub-flows as well as spatial breakdown using different administrative units or zones. Figure 3.43 shows composition of the forest formation flows per Regions and main Landscape Types, while Figure 3.44 illustrates the same for the consumption flows. Figure 3.45 finally focuses in detail on further composition of minor flows of forest consumption both per Regions and main Landscape Types.

Figure 3.43 - Forest formation flows in the Czech Republic per Regions and main Landscape Types.



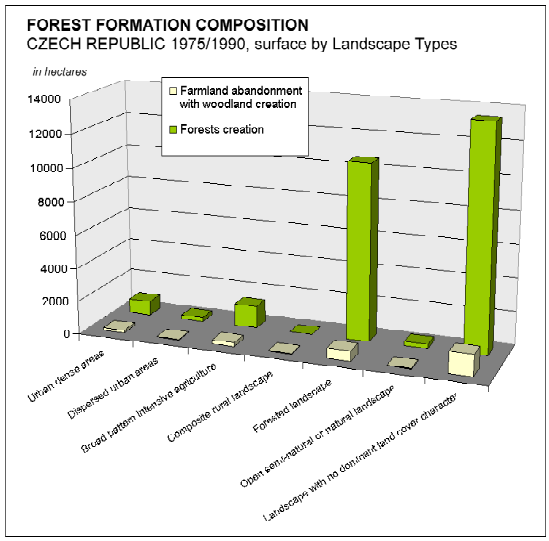


Figure 3.44 Forest consumptions flows in the Czech Republic per Regions and Landscape Types.

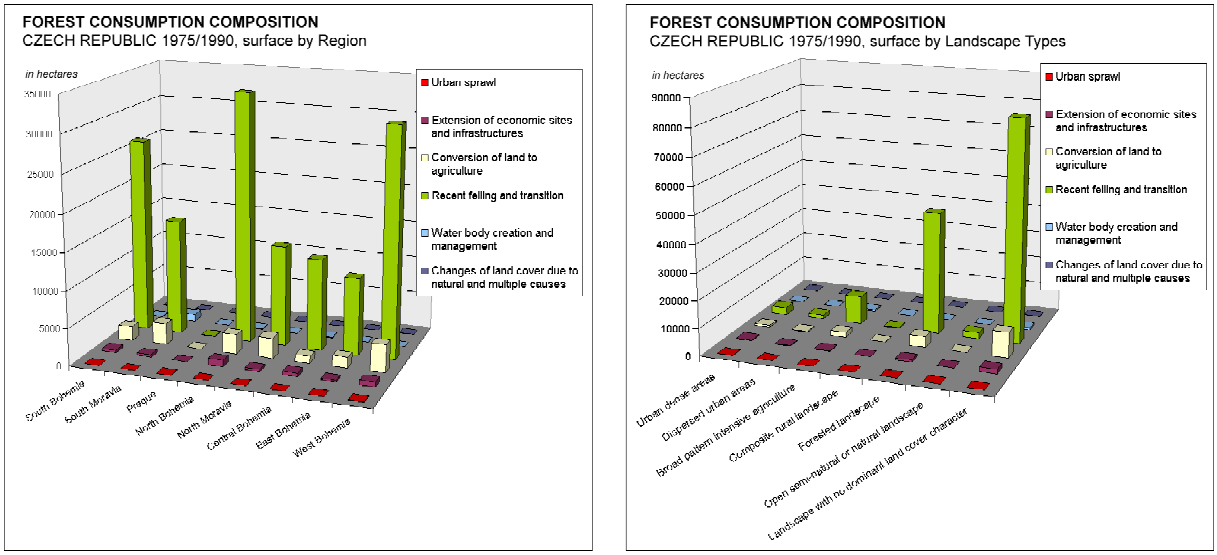

Figure 3.45 Minor forest consumptions flows in the Czech Republic per Regions and Landscape Types.

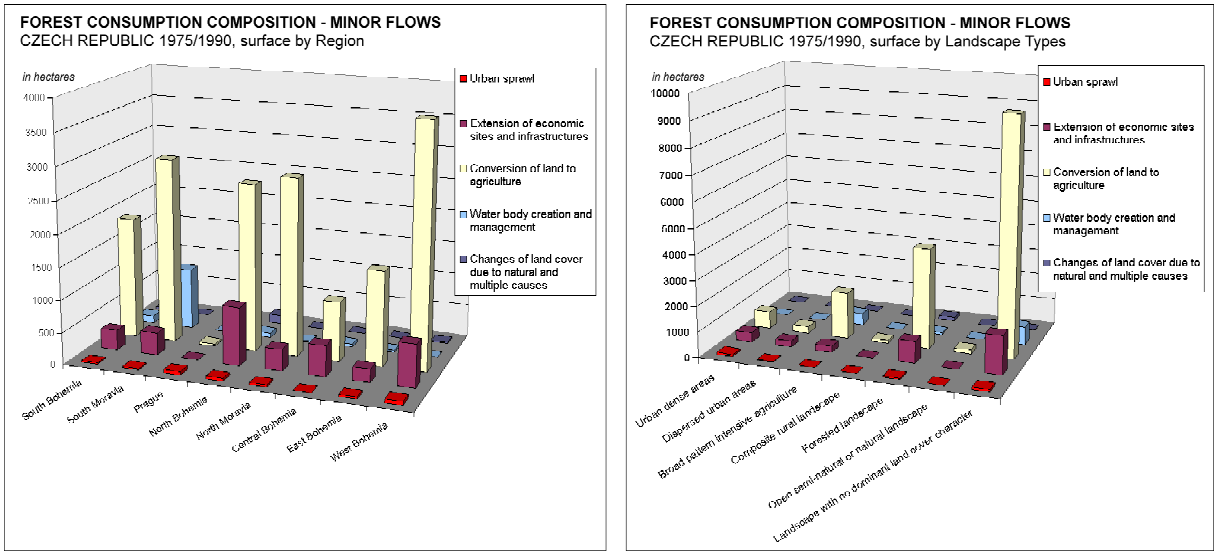
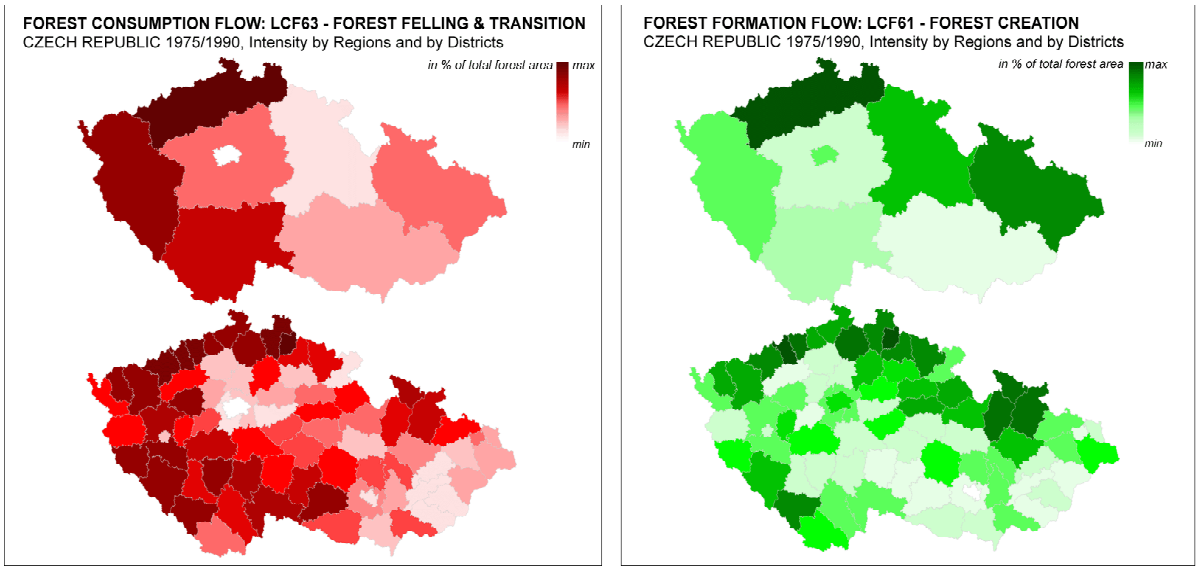


Introduction of spatial aspect and especialy flexibility to exploit various spatial breakdowns using different reporting units like administrative districts or zones (e.g. watersheds etc.) or landscape types brings major advantage into the accounts assessment. More, it also allows mapping of accounting results at most suitable level selected for particular processes under study and production of the targeted indicators as discissed in next chapter. Figure 3.46 shows example of mapping of the spatial intensity of two distinct forest flows, LCF61 “Forest creation” and LCF63 “Forest felling & transition”, for the Czech Republic on two different levels of administration: regions and districts.

Figure 3.46 Spatial intensity of selected forest flows on various administrative level



Examples presented above outlines type of information, which can be obtained by simple analysis of the accounts themselves as proposed and created within the study. Nevertheless, this can be further developed when combining with additional statistics in the focused Targeted accounts as discussed in next chapter.

Part 4: Targeted accounts for Forests – Case study Czech Republic

4.1 Targeted accounts

Targeted or supplementary accounts are constructed for specific purposes, to describe a particular theme or issue. They are derived from basic types of land accounts, and present a more detailed view of the data.

One type of supplementary account is used to give a geographical or zonal breakdown of the data. These accounts are particularly useful in the context of land cover and land use policy, because they allow us to see what geographical contrasts and differences occur between different regions and environments. More importantly they can show how a global indicator is expressed spatially and help in assessing how indicators are interlinked.

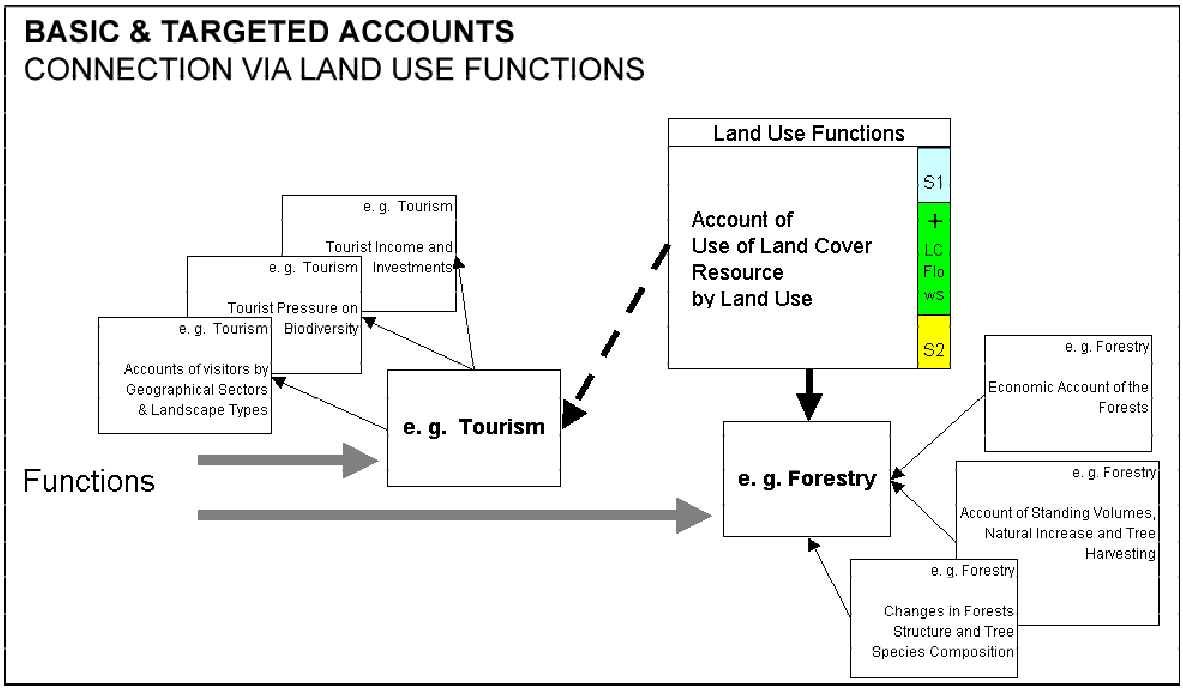
Other types of targeted or supplementary accounts include those, which seek to place a monetary or relative value on the resources or types of change within the flow account. Such accounts provide an important opportunity for the future in terms of showing how the value of various ecosystem goods and services are affected by different types of land cover change.

The so called targeted accounts can be described as a set of accounting tables connected to the LEAC basic accounts via the Land Use Functions account (Fig. 4.1). Such accounts can express stock and change in physical units, such as area or numbers, or there can be some attempt to monetise the account if this is appropriate. The formal relationship of targeted accounts and basic accounts can be made at the level of land analytical units, where detailed and continuous statistics exist, as for population. More often, however, only more general information is available and more aggregated reporting units have to be created. Such accounts could, for example, be developed for large reporting units like administrative regions or river basins when statistics are collected at this level.

The aggregation and linking process required to produce targeted accounts can be made either statistically or, by landscape types, or from multi-variate statistical analysis of grids or of pre-established land units.

The value of targeted accounts is that they allow the calculation of a wider range of indicators that can describe the potentials, the value or the quality of particular natural resources, as well as the intensity of pressure upon them. As a result, they allow the wider use of environmental accounts and indicators in decision-making processes.

Figure 4.1: Connection of LEAC basic accounts and targeted accounts via land use functions



4.2 Targeted accounts for forests

4.2.1 Approaches of forest accounting in published handbooks

Approaches to accounting for forest, as well as possible ways of other natural resources and economic activities accounts construction have been published in several studies. Forest accounts are key element in designing the so-called "targeted accounts for forests" which aim at bridging them with the overall Land and Ecosystems Accounts. It is possible to find types and examples of forest accounts for example in SEEA2003 – "System of Integrated Environmental and Economic Accounting" [36] or in IEEAF (2002) – "The European Framework for Integrated Environmental and Economic Accounting for Forests" [37].

SEEA 2003[38] Accounts for wooded land, timber and forest products

SEEA 2003 introduces following types of forest accounts:

1) Physical accounts
    a) For Forested land
    b) For Timber
2) Monetary accounts for forested land and timber
3) Accounts for forest products
4) Expenditures on forest management and protection
5) Supplementary tables

- 1a) Physical accounts for forested land

Changes in forested land may be brought about by:

– increases in the stock (afforestation and natural expansion);
– decreases in the stock (deforestation and degradation); and
– changes in land classification and reassessment of stocks.

- Terms and definitions

Forested land is defined as land with tree crown cover (or equivalent stocking level) of more than 10 per cent and an area of more than 0.5 hectares. The trees should be able to reach a minimum height of 5 metres at maturity *in situ*. Forested land includes:

– young natural stands and all plantations established for forestry purposes which have yet to reach the crown density of 10 per cent or tree height of 5 metres;

– areas normally forming part of the forested land area which are temporarily unstocked as a result of human intervention or natural causes but which are expected to revert to forest;

– forest roads, cleared tracts, firebreaks and other small open areas, as well as forest nurseries and seed, orchards that constitute an integral part of the forest;

– forested land in national parks, nature reserves and other protected areas such as those of special environmental, scientific, historical, cultural or spiritual interest;

– windbreaks and shelter belts of trees with an area of more than 0.5 hectares and a width of more than 20 metres;

– rubber wood plantations and cork oak stands.

The primary use of forested land is forestry, which includes activities related to the management of forested land and other wooded land for the production and supply of wood and/or other goods and services.

Forested land available for wood supply covers areas where legal, economic, or environmental restrictions do not have a significant impact on the supply of wood. It includes areas where harvesting of timber is not taking place, for example, because of long-term utilisation plans or intentions.

Forested land not available for wood supply includes areas where legal, economic, or environmental restrictions prevent any significant wood production.

Natural forests – Forests with natural species and ecological processes and for which there has been continuity of ecological processes over a very long period of time. The time period of continuity is sometimes quoted as being of more than 200 years but this may not be relevant for all types of forests.

Semi-natural managed forests – Forests in which management has substantially altered the structure and ecological processes but in which growth is still mainly a natural process with no regular and continuous human intervention.

Plantations – Forests for intensive fuel or industrial wood production, planted or artificially regenerated and made up of exotic (non-indigenous) species and/or mono-cultures.

Figure 4.2: An example of physical account table for forested land (1000 ha) in the SEEA

	Forest land available for wood supply	Natural forests	Semi-natural forests	Plantations	Total	Conifers	Broadleaved	Total	Not available for wood supply	Conifers	Broadleaved	**Total**	**Total forest land**

- 1b) Physical accounts for timber

Changes in stocks of timber are due to:
– natural growth of timber (gross annual increment);
– felling of timber;
– natural losses, including catastrophic natural events;
– changes in land classification; and
– reassessment of stock.

- Terms and definitions

Standing volume – The volume of standing trees, living or dead, above stump measured over bark to the top

Growing stock – The living component of the standing volume.

Gross annual increment – The average annual volume of increment over the reference period of all trees, with no minimum diameter. Gross annual increment is thus equivalent to natural growth in a year.

Net annual increment – The average annual volume over the reference period of gross increment less natural losses.

Natural losses – The average annual losses to the growing stock during the reference period due to mortality from other causes than cutting by man.

Annual felling – The average annual standing volume of all trees, living or dead, measured over bark (with no minimum diameter) that are felled during the reference period.

Annual removals – The average annual volume of those fellings that are removed from forested land, other wooded land and other felling sites during the reference period.

Figure 4.3: An example of physical account table for standing timber (volume) (million solid m^3)

	Forest land available for wood supply	Natural forests	Semi-natural forests	Plantations	Total	Conifers	Broadleaved	Total	Not available for wood supply	Conifers	Broadleaved	**Total**	**Total forest land**

- 2) Monetary accounts for forested land and timber

The monetary asset account for timber consists of the opening stock, flows, changes in classification, revaluations and closing stock. Flows include net natural growth, timber removals, timber left in the forests and catastrophic losses. Revaluation records the change in value due to changes in prices of standing timber between the beginning and the end of the period.

- Valuing timber stocks and flows

For monetary accounts it is essential to value timber stocks and flows. Because monetary accounts are not in the centre of our interest we do not describe the methods of valuations here. For the methods of valuation see SEEA 2003[39]

Figure 4.4: An example of monetary account – Asset account for standing timber (million national monetary units)

Changes in classification			
Closing stock			

- 3) Accounts for forest products

As well as the timber harvested, there are other non-wood products, which should be estimated for a full accounting of the environmental yield of a forest. Non-wood products for own consumption and industrial uses are grouped as:

– food (game, berries, fruits, mushrooms, nuts, palm oil, honey, etc.);
– medicines;
– fodder/forage for animal breeding;
– industrial extracts (cork, rubber, gum, tar, chemicals);
– forest animals as agricultural products (wild boar, reindeer, etc.).

- Valuation of non wood products

The volumes of non-wood products are converted from physical to monetary terms using average market prices for the products concerned. These values are imputed for non-wood products for own consumption as well as for products for sale.

39 Handbook of National Accounting.Integrated Environmental and Economic Accounting 2003, ST/ESA/STAT/SER.F/61/Rev.1 (Final Draft)

Figure 4.5: An example of forest products account – Volume and value of all forest products

- 4) Expenditures on forest management and protection

Expenditures on forest protection include conservation of protected forests (according to IUCN categories) and costs of environmental protection activities; such as, the prevention of forest degradation and pollution, and the restoration and reparation of forests. Restoration and reparation costs should be separated from the cost of forestry and logging for purely wood-production purposes. Actual expenditures may represent new investments or maintenance costs. Costs should be split not only by industry but also between the public and private sectors.

Figure 4.6: An example of expenditure on forest management and protection (million national monetary units)

	Private	Forest industry	State	Environmental protection services	Public administration, other public services	Other branches of industry	**Total**	of which public sector

- 5) Supplementary tables

The supplementary tables may be useful to compile when wooded land is being studied in depth. The topics covered are:

– eco-floristic zones;
– protection status (protected (IUCN)/non-protected);
– carbon sequestration;
– age structure of forests;
– forest health;
– biodiversity and ecosystems; and
– non-wood services.

Figure 4.7: An example of supplementary table – Age and timber volumes by dominant species (solid m^3 over bark per hectare; Age in years)

IEEAF – The European Framework for Integrated Environmental and Economic Accounting for Forests[40]

The European Framework for Integrated Environmental and Economic Accounting for Forests (IEEAF) is one of the outputs of Eurostat's Environmental Accounting work. It contributes to various EU-wide and international activities in the context of national and environmental accounts, including the implementation of the European System of Accounts (ESA 1995), the implementation of the new Economic Accounts for Forestry (EAF Rev. 1) and the ongoing revision of the above mentioned System of Integrated Environmental and Economic Accounting (SEEA).

Objective of the IEEAF is to consistently link forest balance sheets and flow accounts for land and timber, forest-related economic activities and the supply and use of wood within the economy, in physical and monetary terms and, in a next step, to also integrate monetary and physical data on non-market environmental and protective functions of forests, biodiversity, the health status of forests, etc.

The manual gives an overview of classifications, definitions, accounting frameworks and valuation issues. The classification of forest-related assets is reviewed, as well as the treatment in national accounts of the changes that affect these assets (transactions, other changes in volume, etc.). Physical accounting frameworks and indicators as well as valuation issues of forest-related assets in ESA/SNA are then analysed, with special focus on (wooded) land and stocks of standing timber.

IEEAF proposals are made for integrated environmental and economic accounts for forests. These accounts form a "forest satellite account" to the national accounts allowing for the linking of national accounts data to other environmentally oriented instruments (indicators, land accounting matrices, etc.). The final objective is to describe interactions between economic activities and forests as natural media and to integrate environmental and economic concerns about forests in a consistent and comprehensive way.

The proposed framework covers:

– a core classification of forest-related assets, wood products and related industries,

– balance sheets of forest-related assets, in monetary and physical units, integrating the description of all changes that affect forest-related assets,

– monetary accounts for activities and transactions related to forests (forestry, logging, etc.), including forest protection and management activities,

– supply and use tables, in monetary and physical units,

– mass balances and flows of residuals accounts, in physical units.

40 The European Framework for Integrated Environmental and Economic Accounting for Forests- IEEAF. Luxembourg: Office for Official Publications of the European Communities, 2002, Cat. No. KS-BE-02-003-EN-N

Types of the IEEAF accounts:

1) Flow accounts
    Simplified NAM
    Monetary flows
    Material flows and balances
2) Balance sheets and changes in assets
    Classification of assets
    Changes in balance sheets
3) Flows of residuals
    Objective and general structure
    Description of residual flows
    Application to forests: classifications
    CO2 balances
4) Non-wood and non-ESA/SNA functions of forests
    Non-wood products of forests
    Non-ESA/SNA functions

Twenty tables have been drafted for a first implementation of IEEAF. They cover the main aspects of the IEEAF:

– Balance sheets for land and standing timber (physical balances of wooded land areas, monetary balances of wooded land areas, physical balances of standing timber and monetary balances of standing timber).

– Table for defoliation.

– Output related to wooded land, detailed accounts for forestry and logging and economic accounts for forestry and logging.

– Supply and use tables, in physical and in monetary units.

– Material balances.

– Tables describing origins and destinations of waste containing wood or paper, of black liquors and the corresponding wood contents.

The set of tables is inspiring but only balance sheets (see below) were at least partly applicable (especially due to low availability of statistical data) for our study.

Figure 4.8: Forest balance: area and wooded land (1000 ha or million national monetary units) in IEEAF

	Forest and other wooded land							Other land	Total land

4.2.2 Land targeted accounts for forests and their specifics

We have introduced basic (core) accounts on one side and special forest accounts on the other side in the previous parts of the report. Targeted forests accounts have their special nature as compared to both core land cover accounts and conventional forest accounts.

Targeted accounts enrich the core land cover accounts because they record the development of land cover in relation with socio-economic functions of the territory. They reflect land use functions of the territory and this way allow us to study the influence of the use of land on the land cover and its development. For the list of land use functions see Fig. 4.10.

Figure 4.10: Nomenclature of land use functions as proposed for LEAC[41]

UF1 Residential, incl. services
UF2 Commercial
UF3 Transport
UF4 Industrial production
UF5 Energy production
UF6 Mining & quarrying
UF7 Waste dumping
UF8 Water management
UF9 Farming, food production
UF10 Forestry
UF11 Recreation & Tourism
UF12 Nature conservation
UF13 Other uses

Note: The proposed nomenclature of Land use functions of forestry is presented in the section 4.4.2 Land use functions of forestry and targeted accounts.

For the purpose to reflect land use functions the targeted accounts use statistical records for several types of units. Forest targeted accounts use forest statistics for this purpose. The advantage is in the wide geographical breakdown of targeted accounts. They can be constructed as for administrative units on several levels (country, region, district) as for units natural for land cover studies like landscape zones, forest regions or river basins. This way the relation between administrative units by which usually statistics are recorded and natural units is made and land use functions development and influence can be studied in these natural units.

In comparison with the above proposed forest accounts (SEEA, IEEAF) the targeted forest accounts have to be usually simplified as long as not all statistics can be available by natural zones (transferable into them).

---

(2003): Integration of geographical and statistical data in the environmental accounting framework; methodological development based on two case studies Action 2: Integration of environmental accounts in coastal zones; case study of tourism, Barcelona 2003, Contract n° 200141200017, EUROSTAT

4.3 Framework and data sources for forest targeted accounts in the Czech Republic

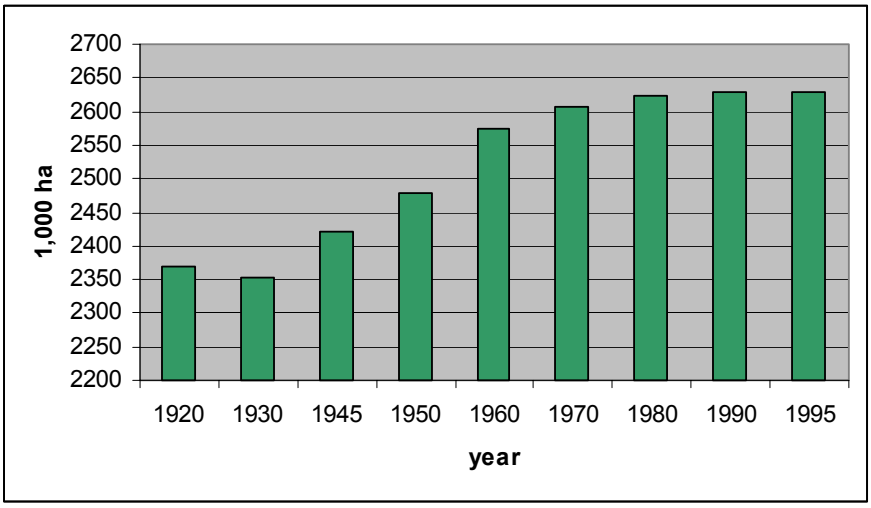
4.3.1 Czech forests – development and state[42]

Long-term development of forest coverage in Czech lands is recorded in the following figures.

Figure 4.11: Forest coverage development in the Czech lands

year	1790	1865	1910	1990	1995
Forest coverage (%)	25	28	30	33.3	33.3

Figure 4.12: Forest land area development in the Czech Republic in 20th century



Czech forests have been mainly influenced by several essential driving forces during the 20th century:

– expropriation of private forests after 1948

– poor management by State after expropriation

– development of industry and energy (brown coal power plants) that resulted in high production of SO_2 emissions (local and long-distance transport from Germany) and forest damage in the north parts of the country (which belongs to the so called "Black triangle")

– breakdown and the return of market economy after 1989

– restitution of forests

42 The main source of the data and information in this chapter is Report of Forestry of the Czech Republic 1996. Compiled by the Forest Management Institute, Brandýs nad Labem (http://www.uhul.cz/zelenazprava/1995

– current subsidy system for forest management (subsidies to owners for the purpose of afforestation and forest management)

– bark beetle calamity in 1990s (damage of protected forests in the south parts of country – Šumava national park)

– good nature preservation low from 1992 (special forest management in strictly preserved areas)

Role of forestry in national economy

Significant change of political system in 1989, as well as significant changes in Czech forestry have been recorded between 1975 and 1990 and further. In the Czech Republic recession as a result of period of transition has finished. the Czech Republic has became a member of the OECD. Macroeconomic results of the Czech Republic has enabled to submit an application for membership of the EU. The CR has become an interesting country for foreign investments as well.

Forestry sector produced 0.8 % of GDP in the Czech Republic in 1990. This percentage did not reflect real importance of forestry for society because benefits of non-wood functions were not included. Forestry employed 0.7 % of total number of national work force (in 1975 the number was 0.5%), investments in forestry sector were 0.4 % of total volume in the Czech Republic.

Forest management

- Changes in Forest Ownership

Because the great majority of Czech forests before 1989 belonged to State their manager was the State organization "*Forests of the Czech Republic*". The other part of the forests about which data sources are practically not available were military forests under management of the Czech army.

While in 1975 and 1990 private property of forests practically did not exist the restitution process continued during 1990s. In 1995 83% of 158,000 claims of individuals was authorized which covers more than 687,000 ha. The average area of forest holding in this category is only 3 ha. In restitution of forests to communities, more than 90% of claims was completed. Restitution of properties of forest communal cooperatives was started (about 22,000 ha is claimed). Return of church forests has not been legislatively regulated yet.

Forest condition

Area of forests in the Czech Republic has been increased by 656,000 ha since 1790 when the first data were available. The percentage of forest land has enlarged from 25% to 33%. Sylvicultural system has been changed. During the last 90 years proportion of high forests has increased by 10% up to 99.8%. Since 1950 percentage of broadleaved species has increased from 12.5% up to 21.8%. This trend is continuing. Since 1920 average rotation has risen by more than 20 years (and by more than 10 years since 1950) up to the present level of 114.6 years. The age composition shows some anomalies. Low percentage of 2^{nd}–5^{th} age classes is unfavourable (caused predominantly by high volume of salvage felling without consequent reforestation), as well as high percentage of 6^{th}–9^{th} age classes as a result of mass pest outbreaks (mainly of nun moth) in the beginning of this century and the above average percentage of older age classes. The unbalanced age structure will influence volume, proportionality and assortment composition of harvesting in the period after 2040. Therefore, it is desirable to regulate intentionally volume of felling. Growing stock volume amounts to 595 millions m^3 and is nearly as twice as much compared with 1950. Mean annual increment is higher than 16 millions m^3, i.e. more than 6 m^3 per ha of forest stands area.

Relation of Forestry and Environment

- Air pollution

One of the most serious environmental problems of forestry in Czechia was during the last decades of the 20th century air pollution. Emissions of SO_2 were reduced between 1980 and 1993 by 31.7%. In the period 1992-1995 the emissions of the main pollutants from stationary source decreased by 19% and total emissions of solid pollutants by 36%. Continuous reduction of selected power plants production and the installation of the precipitators (Prunéřov I, II, Počerady, Ledvice) caused further reduction of sulphur emissions.

The Czech Republic implements its international commitments concerning reduction of SO_2. Further decreasing should be 72% in 2010 related to 1980 state. The state expended CZK 253 mil. for reclamation and torrent control in forests. The development of damage degree due to air pollution shows following figures.

Figure 4.21: Average damage degree in conifers forest stands

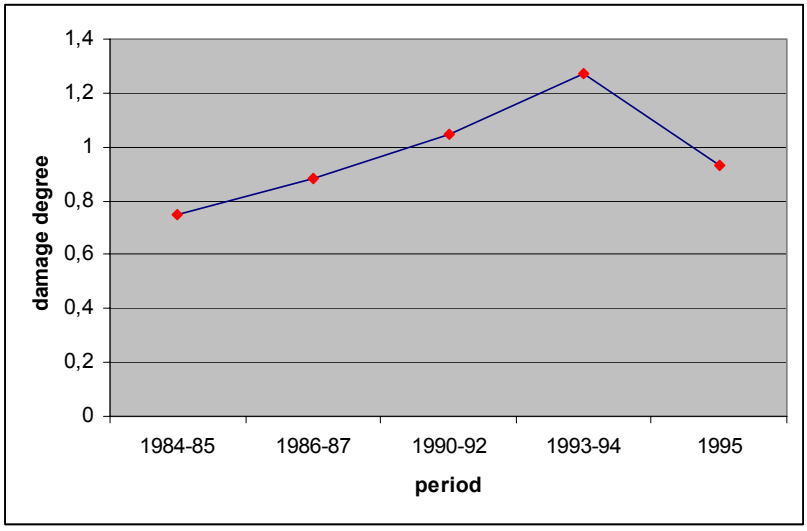

Figure 4.22: Development of air pollution damage of forest

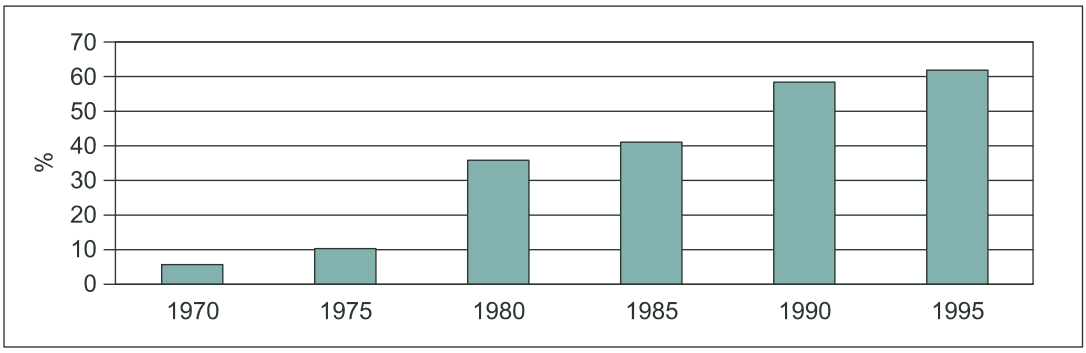
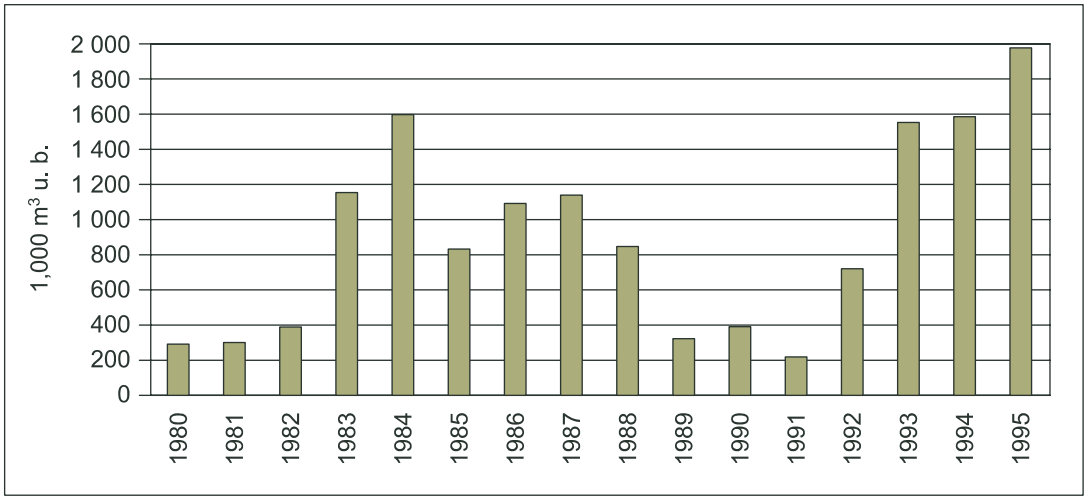


- Insect attacks

As a result of suitable weather conditions and some difficulties in forest management decisions and practice the Bark Beetle calamity took place in some areas. One of the most affected area is Šumava national park. The evidence about the development of the calamity until 1995 gives the amount of Norway Spruce timber attacked by Bark Beetle.

Figure 4.23: Volume of wood infested by Bark Beetle in Norway Spruce stands



- Areal protection

Special forest management with the goal of preservation of the most valuable forest ecosystem is being applied in the forests in protected areas. The share of forests in these areas and the zones of immission damage summarizes following table.

Figure 4.24: Forests of big protected areas with nature preservation function in the Czech Republic

Economic results of Forestry

Some of the available economic results of forestry from 1985 and especially the results from 1990 and further are in the tables below. It is important to stress that the prices during socialist period were not market prices and that economic results were purposely misrepresented. This is a reason why it is not possible to compare reliable the results before and after 1989.

Figure 4.25: Forest management average costs in CZK (1995 prices, 1€=33CZK)

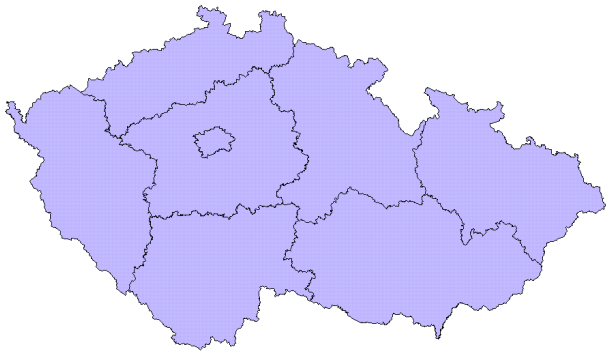
4.3.2 Statistical data sources for forest targeted accounts in the Czech Republic

Except of basic accounts, land cover flows and landscape types data inputs that are described above in the report also statistical data are essential for targeted accounts construction.

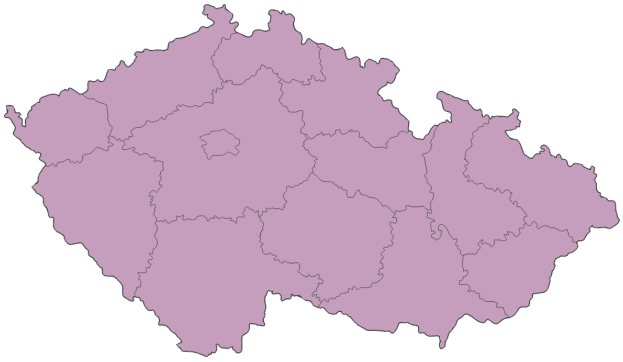
Before 1989 the forest statistics were published by *Czech Statistical Office (CSO)* and by the organization of the Ministry for forest and water management – *Forest Management Institute (FMI)*. The statistics were not fully reliable because socialist regime misrepresented the data, especially for the purpose to pretend better economic results. This is very important information and means we use for targeted accounts data from two such different years (1975, 1990) with different levels of data reliability.

Figure 4.28: Administrative regions in the Czech Republic (valid until the end of 1992)



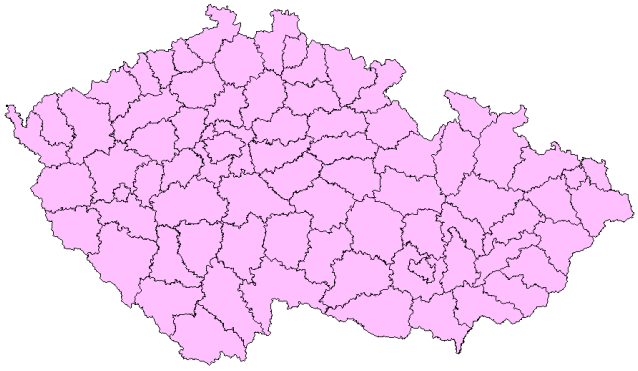
The statistics were produced for the *country level* and very elementary statistics for the level of the *administrative regions* (see Fig. 4.28). These administrative regions were valid until the end of 1992 and they were replaced by wholly different regional system then – new administrative regions (NUTS 3) – compare the figures 4.28 and 4.29.

Figure 4.29: NUTS 3 – administrative regions in the Czech Republic (from the beginning of 1993)



After 1989 the Czech *Statistical Office* (http://www.czso.cz) continued publishing forest data on country and regional levels until 1993. That is why we can use their data sources also for 1990. From 1993 onwards the forest statistics are published for new regions (Fig. 4.29) by CSO. The *Forest Management Institute (*http://www.uhul.cz*)* have also started to produce data for new regions (NUTS 3) and also for district level (NUTS 4) – Fig 4.30 from 1994. These data are valuable because they report about the situation in relative small territorial units and in spite of the fact that in national territorial system the district have been cancelled (from 2003) forest statistics will be published for district level also in the future, so the comparisons of the development (including targeted accounts) on this level will be possible. Unfortunately our study is concerned with previous period so we cannot use districts as reporting units.

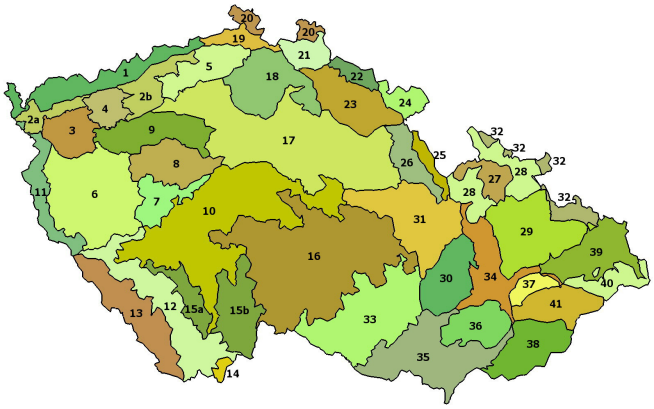
Figure 4.30: NUTS 4 – district in the Czech Republic



It is important for forest accounting to mention that the *Forest Management Institute* works also with special reporting units – so called *natural forest regions* (NFR). These regions are divided on the basis of common geologic, climatic, orographic and phyto-geographic conditions. In this way are delimited relative naturally homogenous zones – see Fig. 4.31. In relation to the NFR, the regional plans of forest development (RPFD) define forest management principles. The RPFD data are shared with the *Forest Management Institute* (FMI) through the Information and Data Centre (IDC). It will be possible to use the data of IDC – "Information about the state of forests" – for forest accounting in the future. They are

available for the country level (NUTS 1), NUTS3 and NUTS 4 from 1994 (up to now until 2000) and for NFR from 1998 (up to now until 2000).

Figure 4.31: Map of natural forest regions (NFR)



Other important note is that no data, except some basic statistics on the country level, were published for military forests that represent about 5-7% of forested land and these forests are certainly incorporated in CORINE database. This produces certain inconsistency for use of forest statistical data in combination with CORINE data set for forest targeted accounts calculations. Even now only basic information about the military forest are available for FMI.

Further inconsistency could appear when we use data of the Czech *Statistical Office* that are published for "forest land" that is not just "forested" land but this category incorporates also other areas like temporary deforested areas that are not classified as "forests" in CORINE data set. Extensive discussion about the problem of the compatibility of national land use/land cover statistics with CORINE land cover records are published in Feranec et all. (2001)[43].

To prevent this inconsistency, when possible, we work not with "forest land" but with "forested land" that has been recorded in the data of FMI and represents only land with tree cover, it means practically the same category like is the category 31 – forests in CORINE nomenclature. Unfortunately as the following table shows in 1975 the result of CORINE classification is closer to the category forest land (CSO) than to the forested land (FMI). This can be caused by inaccuracy of the CSO data sources as we mentioned above or in general by different definitions of forests in CSO, FMI sources and CORINE nomenclature.

Figure 4.32: Comparison of forest nomenclature and area in different data sources for the Czech Republic (ha)

	forest land (CSO)	forested land (FMI)	forests (CORINE)
1975	2613098	2570483	2596992
1990	2629905	2582780	2455398

43 Feranec, J. et all. (2001): Výsledky porovnania národných štatistík Česka, Maďarska, Rumunska a Slovenska s údajmi CORINE land cover. Geodetický a kartografický obzor, 47/89, 2001, No. 8-9, pp. 208 – 213

When we compare the content of forest statistics for 1975 and 1990 we can find rather similar records for the country level, especially in the CSO statistic. Very problematic situation is in the records matching on the regional level. During the time of 15 years the statistical tables have been significantly changed. That is why we were able to produce just very limited amount of forest targeted accounts for this level.

It is obvious from all the above mentioned information that forest statistics data availability and compatibility for 1975 and 1990 are rather problematic. It is the reason why even on the country level the construction of supplementary forest tables was problematic and why the tables had to be simplified in comparison with above introduced tables suggested for this purpose in SEEA 2003[44] and IEEAF[45].

There is a good possibility to improve forests accounting in the Czech Republic in the future especially from 1994 further especially because the above mentioned data will be published by FMI. In any case EUROSTAT should start a wider discussion with CSO and FMI about which records should be stored for this purpose. Even when the level of data records will be appropriate, the content of the statistics records is not at this time sufficient for the construction of forest targeted accounts adequate to SEEA 2003 or IEEAF proposals. We discuss more the data needs and data gaps for forest accounting in Czech statistics in the next parts of the study.

List of the data sources used for the targeted forest accounts construction:

1975

– *Forest Management Institute* (1975): Forest Inventory 1975. Ministry of the forest and water management of the Czech Socialistic Republic.

– *Czech Statistical Office* (1976): Czech statistical yearbook 1976 (state in December 31st 1975).

– *Forest Management Institute* (1996): Report of Forestry of the Czech Republic 1996. Brandýs nad Labem (http://www.uhul.cz)

1990

– *Forest Management Institute* (1991): Forest Inventory 1990. Ministry of forests and water management of the Czech Socialistic Republic.

– *Czech Statistical Office* (1991): Czech statistical yearbook 1991 (state in December 31st 1990).

– *Forest Management Institute* (1996): Report of Forestry of the Czech Republic 1996. Brandýs nad Labem (http://www.uhul.cz)

4.4 Targeted forest accounts for the Czech Republic – results of the case study

One of the main goals of the project was to produce targeted (supplementary) accounts for forests of the Czech Republic by suitable reporting units. This chapter is an output of theoretical and practical proposal of forest targeted accounts set based on land use functions and functions of forestry on country level, by landscape types and by regions that were only administrative units for what the forest statistical data in 1975 and 1990 were available.

4.4.1 The use of land cover by functions

As we mentioned before one of the specifics of targeted accounts is that they reflect the use of land cover by functions. Following table shows the Supply&Use of land cover resource by Land Use Functions in general for all land cover types.

Figure 4.33: Supply&use of land cover resource by land use functions

SUPPLY & USE OF LAND COVER RESOURCE
BY LAND USE FUNCTIONS

3.2+3.3	*Shrub and other semi-natural land*															
4	Wetlands															
5	Water bodies															
D - TOTAL FINAL SURFACE ~1990 (D = A+B+C)																

This describes the use of land by the function and the way it expands or shrinks over the accounting period. These changes may result in formation of a new land cover, e.g. the expansion of forestry resulting in conversion of land to forests. But it is not always the case and the change in the area of a function may take place without any modification of land cover. More generally, the possible multiple uses of a given land cover requires a separate accounting of changes in use that does not result in the formation of a new cover. The new protection of a forest (an extension of the Use Function "Nature protection") does not generate loss of forests, although it may have consequences on the function "Forestry". Consequently, the total allocation of land to these functions is important in environmental and economic assessment and in policy-making, in particular when multiple uses result in possible conflicts of use.

The basic equation of the Supply & Use of Land Cover Resource by Land Use Functions is:

EQUATION ***Initial surface***

+ Net Formation of Land Cover by Use

+ Net Extension of Use without Formation of Cover

= Final surface

This equation is valid for each individual function. When addressing several functions, overlaps generally happen due to possible multiple uses. Therefore, an additional column is necessary to adjust the total by deducing the multiple uses and maintain a formal identity between the sum total of land use and of land cover.

This last point is disputable when considering the Change in Use without Formation of Cover. As long as the total surface depends on the number of functions identified, it seams reasonable not to present results for this total. However, the land used by each individual function is presented and can always be added to others for specific analysis.

Based on the general table of the use of land cover by functions – Fig. 4.33 specific table for forests – Supply & Use of land cover resource by land use functions in the case of forests - have been constructed – see following Fig. (4.34).

Figure 4.34: Supply&use of land cover resource in the case of forests

Final Surface 1990									**2462654.6**

4.4.2 Functions of forestry and land use functions

The functions of "Forestry" can be in turn detailed for analytical purpose. It corresponds to the concept of "Targeted Accounts" introduced earlier in the report. These accounts present, first, details of land cover flows related to specific zones, landscape types, and environmental issues. Second, they organise the information on a given function in the framework of accounts of land use functions.

Like in the case of tourism also for forestry classification of sub-functions has been established and basic table showing the connection of forest functions and land use functions has been constructed:

Figure 4.35: Functions of forests and land use functions

Forest functions	Land use functions

water protection	UF8 Water management
Socio-economic functions	
Recreation & tourism	UF11 Recreation & Tourism
provision of employment	UF13 Other uses
Research & education	UF13 Other uses

4.4.3 Proposal of targeted forest accounts

In the pilot studies on the feasibility of LEAC with CORINE Land Cover, 2 issues have been identified for tests: Tourism on the coastal zone and forestry for the Czech Republic. The first test has been finished already and is published in the first part of this report[46]

46 Weber, J. L., Paramo, F., Breton, F. Haines-Young, R. (2003): Integration of geographical and statistical data in the environmental accounting framework; methodological development based on two case studies Action 2: Integration of environmental accounts in coastal zones; case study of tourism, Barcelona 2003, Contract n° 200141200017, EUROSTAT

In the case of forestry, the test has also been twofold: methodology and statistical implementation. Though the methodological framework tests are limited due to difficulties in collecting statistics they can be considered as a good base for further development. The set of tables show clearly how the various sub-accounts match and what is the interest in bridging them together. Issued from the theoretical approaches and outputs of tourism part the outputs in the case of forestry were further developed. The statistics have been collected and real targeted forest accounts for the Czech Republic (country), regions in the Czech Republic and also for landscape types as natural units were calculated in two levels:

– theoretical level – tables without numbers in blue colour

– practical level – usually simplified tables according to statistics availability – tables with results of calculations (by landscape types, regions and country).

The list of all the tables of proposed targeted forest accounts and the tables follow.

The construction and factual problematic of individual proposed accounts in theoretical and practical levels are further widely commented (chapter 4.4.4).

4.4.4 Remarks and data needs for proposed forest targeted accounts

According to land use functions and related functions of forestry, the above theoretical framework of forest targeted accounts has been established. Then using available LEAC as well as statistical data we have prepared real samples of the accounts. In this chapter we comment more these proposed targeted accounts (theoretical and real), their specifics and data needs for their construction. The parts that are on our opinion the most important for Eurostat are in bold.

- Theoretical proposal of account: Forests by dominant landscape types (Fig. 4.36)

construction remarks:

– in theoretical level forests can be divided into conifers, broadleaved and mixed in the dependence of CORINE data set legend level

– the difference between total initial and final surface could be also incorporated for quick information about the development of forests area changes in individual landscape types during the period

- Real table: A) Forests by dominant landscape types

construction remarks:

– because of the legend level difference in 1975 (level 2) and 1990 (level 3) the diversification between conifers and broadleaved was not incorporated

– also +/- flow of LCF 62 (change between conifers and broadleaved forests) is not incorporated

factual remarks:

– in accordance with the trend of the whole the Czech Republic in most of the landscape types forest area decreases between 1975 and 1990

– an exception are landscape types B13 and C11 – increase of forest is due to LCF 61 – Forest creation

  - statistical data needs:

  statistical data not needed

- Theoretical proposal of account: Forests by regions and/or forest regions (Fig. 4.37)

construction remarks:

– in theoretical level forests can be divided into conifers, broadleaved and mixed in the dependence of CORINE data set legend level

– the difference between total initial and final surface could be also incorporated for quick information about the development of forests area changes in individual landscape types during the period

– this account can be also constructed for other administrative units (for example districts)

factual remarks:

– statistical adjustment between CLC and forest statistics can be incorporated but the explanation of the difference is not easy because the differences can be caused by different definitions of forest, or by incorrect statistical records or by classification accuracy problems

– this account in combination with forests by dominant landscape types creates the "bridge" between CLC and forest statistics

- Real table: A) Forests by regions

construction remarks:

– because of the legend level difference in 1975 (level 2) and 1990 (level 3) the diversification between conifers and broadleaved was not incorporated

– also +/- flow of LCF 62 (change between conifers and broadleaved forests) is not incorporated

factual remarks:

– in accordance with the trend of the whole the Czech Republic there is clear forest decline in all district of the Czech Republic, except Prague

– the most significant decline was in Northern Bohemia (damage due to air pollution)

– the difference between CLC and forest statistics in 1990 is relative high, especially in Northern Bohemia (statistics show 11,02% higher area than CLC)

– the reason of the difference can be in different definitions of forests (in Northern and also Eastern Bohemia there was in 1990 extensive area of temporarily unforested forestland – damaged by air pollution – that is in statistics recorded under forest land still while on satellite image forests cannot be detected)

  - statistical data needs:

  statistical data needed only for statistical adjustment – **area of forested land by regions (districts)**

- Theoretical proposal of account: Forest composition (age/structure/ownership/monetary value) by regions and/or forest regions (Fig. 4.38)

construction remarks:

– forest composition can be expressed by several ways; construction of individual account depends on the variable of expression

– can be constructed for administrative units or for natural units (forest regions)

- Real tables

A) Age structure by regions

construction remarks:

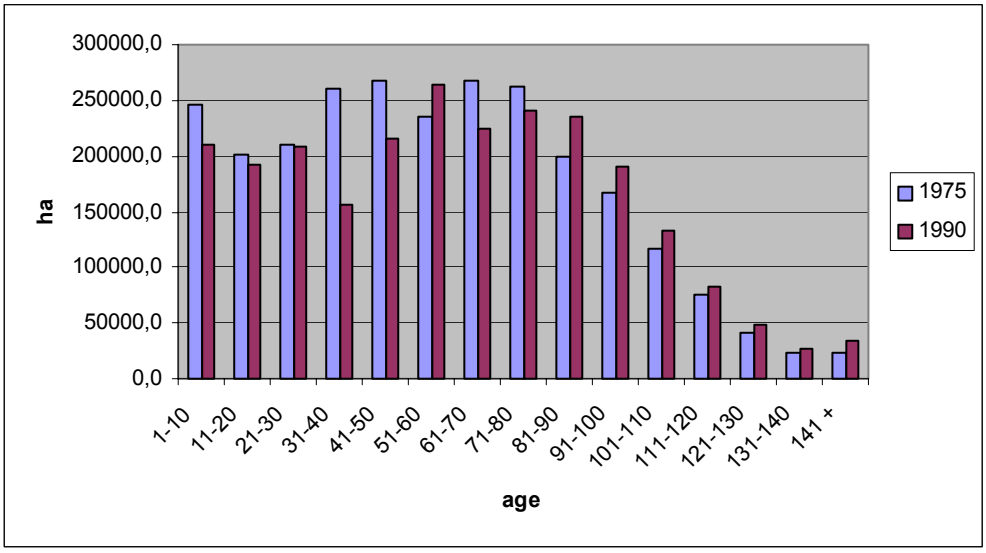
– statistical records in % can be used to recalculate age structure for CLC

– can be constructed for administrative units or for natural units (natural forest regions)

factual remarks:

- as following figure shows Czech forests are getting older during the period under observation – area of younger age groups decreases and area of older age groups increases

Figure 4.45: Age structure development in the Czech Republic



B) Categorization of forests in the Czech Republic

construction remarks:

– the numbers for CLC are recalculated using statistics (% share of the categories)

– during the period some changes in types of categories occured but for the future there will be stable categories

factual remarks:

– high decrease of protection forests (and high increase of special purpose forests) is caused partly due to changes in categories definitions

C) Owners structure of forests in the Czech Republic

construction remarks:

– the numbers for CLC are recalculated using statistics (% share of the categories)

factual remarks:

– there was still very low share of private forests in 1990 but until 2000 the situation has changed dramatically – there are more than 20% of private forests in the Czech Republic now and very low share of agro-cooperative forests

D) Sylvicultural system of forests in the Czech Republic

construction remarks:

– the numbers for CLC are recalculated using statistics (% share of the categories)

- Statistical data needs for forest composition targeted accounts (by districts, regions, natural forest regions)

1) **forested area divided by conifers, broadleaved and total (in ha or %)**
2) **age structure by age groups divided in conifers, broadleaved, total and by tree species**
3) **categories of forests (commercial forests, protection forests divided in water, soil and other types of protection, special purpose forest) divided in conifers, broadleaved and total (in ha or %)**
4) **owners structure (state, communal, church, co-operative, foundations, nobility, other private, agro-cooperatives, other) divided in conifers, broadleaved and total (in ha or %)**
5) **sylvicultural categories (high, medium, coppice forests) divided in conifers, broadleaved and total (in ha or %)**
6) **changes in classification of forests (caused by low or by other reasons)**

- Theoretical proposal of account: Forest stocks and use by regions and/or forest regions (Fig. 4.39)

construction remarks:

– the account is a type of flow accounts; in this case it is based on statistical data of affoestation (plantations, natural increase, colonisation) and deforestation (felling, thinning, loss due to storms, floods, insect calamities, degradation by pollution etc.)

– this account can be constructed as annual – then the data from initial and/or final year are sufficient

– when the account is constructed for the whole period under observation – cumulated account – the data from each year inside the period are needed

– when the units of the account are different from areal extent units (ha), the account has to be based on statistics data and cannot use CLC data (recalculate the values for them)

- Real tables

A) Annual felling by tree species by regions

construction remarks:

– this table is the annual type of the account

– the table is based on statistical data (in 1000 m^3)

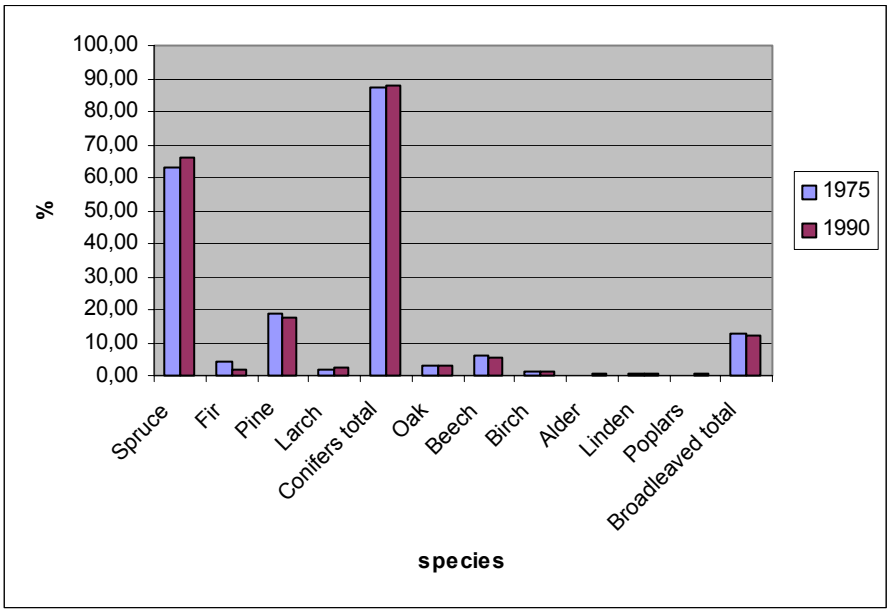
factual remarks:

– the total annual felling in the Czech Republic was more than 10% higher in 1990

– the total annual felling in regions was higher in 1990 except Northern Moravia

– the share (in %) of the tree species on total felling was on the country level higher in 1990 in the case of spruce, larch, conifers in total, alder, linden and poplars, lower in the case of broadleaved in total (see the following figure)

Figure 4.46: Annual felling by tree species in the Czech Republic



B) Annual afforestation by regions

construction remarks:

– this table is the annual type of the account

– the table is based on statistical data

factual remarks:

– while total afforestation in the Czech Republic was higher in 1990 the tendencies in regions were different; higher afforestation in 1990 in Southern, Eastern Bohemia and in the both Moravian regions and lower in other regions

Non-wooded forestland available for afforestation in the Czech Republic -annual balance

construction remarks:

– this table is a special account on country level that shows the extent of non-wooded forest land available for afforestation in the beginning and in the end of the year and the increment and decline of this land during the year

C) Development of real total felling in the Czech Republic – cumulated balance

construction remarks:

– this table is the cumulated type of the account which needs data for each year during the period under observation

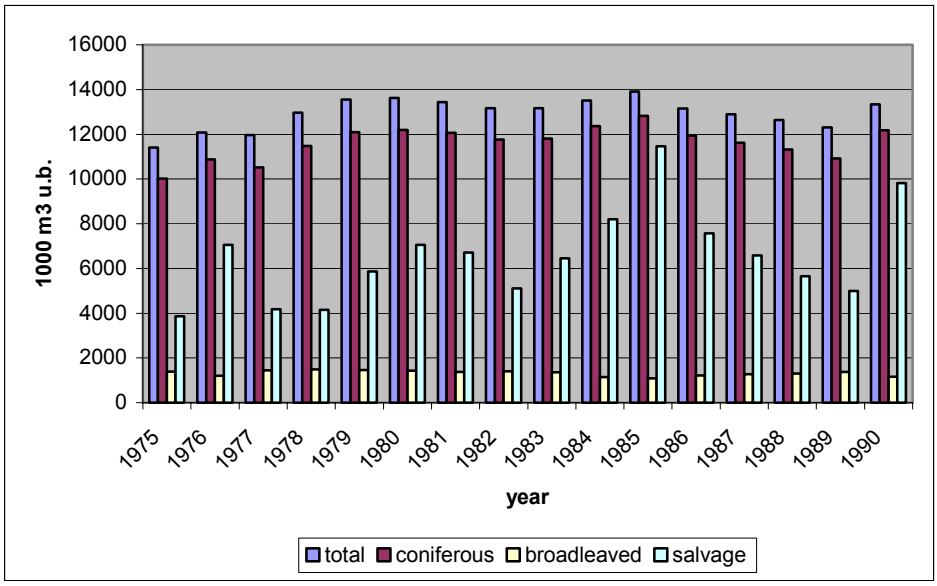
– because of the data and time high demand it is difficult to calculate for lower than country level

– the table is based on statistical data

factual remarks:

– the peak of the felling and salvage felling in 1985 was caused by the forest damage due to air pollution (see the following picture).

Figure 4.47: Development of real total felling in the Czech Republic



- Statistical data needs for forest stocks and use accounts (by districts, regions, natural forest regions) – in m^3 (1000 m^3) or ha

  1) **standing stock**
  2) **afforestation- plantations, natural increase, colonisation**
  3) **deforestation – felling, thinning, cleanings, loss due to storms, floods, insect calamities, degradation by pollution etc.**
  4) **the data should be available for the initial and/or final year of the period under observation – for annual accounts or for all years of the period – for cumulated accounts**
  5) **all the data can be divided in conifers, broadleaved and total, or by forest categories, or by owners structure, by age, by species etc.**

- Theoretical proposal of account: Supply and use of wood by country, regions, natural forest regions (Fig. 4.40)

construction remarks:

– this table is based on statistics (in m^3)

– there are two main information in the table – total supply (crated from national supply and import) and total use (by types of use)

– can be constructed as annual or as cumulated account

- Real tables

A) Wood supply by regions

construction remarks:

– Statistics of *Forest Management Institute* were a source of the data for this table; the numbers do not include military forests – that is why total wood supply is lower than in the next table

– the table is based on statistical data

factual remarks:

– wood supply in 1990 in the Czech Republic and all regions, except Northern Bohemia and Northern Moravia was higher than in 1975

B) Annual wood supply in the Czech Republic

construction remarks:

– Yearbook of *Czech Statistical Office* was a source of data in this table

– the table is based on statistical data

factual remarks:

– except pulp and fuelwood in the cases of all other wood products the supply of broadleaved was lower in 1990 (also the total supply)

– supply of products from conifers was higher in 1990 in total, in the case of round-wood, pulp, industrial wood and fuelwood

– the validity of statistical data from 1975 is problematic

- Statistical data needs for supply and use targeted accounts (by districts, regions, natural forest regions – NFR) – in m^3 (1000 m^3)

1) **national supply of wood, supply from regions (districts, NFR) divided by conifers, broadleaved and total**
2) **export, import of wood (can be divided by types of wood products and/or by countries)**
3) **use of wood by types of wood products (timber, pulp, firewood, round-wood, mine props, poles, industrial wood etc.) – can be divided in products from conifers, broadleaved and total**

- Theoretical proposal of account: Forest non-wood products by regions and/or forest regions (Fig. 4.41)

construction remarks:

– dependent on statistical sources and/or estimations

factual remarks:

– statistics are usually available only for game or animal breeding or in general by products that were extracted from the forests, but the total amount of non wood products can never be calculated, hardly estimated

– non wood products can have also other values like recreational, esthetical etc.; these values can be evaluated only by estimations and special methods as they do not have any market prices

- Real tables

A) Trap hunting in the Czech Republic

factual remarks:

due to landscape damage and pollution partridges in the Czech Republic almost disappeared – the evidence is low amount of partridges hunted down in 1990

B) Hunting – shooting in the Czech Republic

factual remarks:

– interesting is increase of hunted pieces of deers, fallow deers and mufflons and at the same time decrease of hunted pieces of roebucks

– very high was in 1975 the number of hunted hares and pheasants; their quantity in open nature decreased until 1990 for the same reasons as in the case of partridges and also because of excessive hunting

  - Statistical data needs for non-wood supply targeted accounts (by districts, regions, natural forest regions – NFR) – in pieces, tons, or current prices

1) **supply of non-wood products – mushrooms, berries, medicinal plants, game – can be divided by species**
2) **animal breeding results (by species)**
3) **other forest non-wood products**

- Theoretical proposal of account: Forests and protection by landscape types or regions or forest regions (Fig. 4.42)

construction remarks:

– it is possible to divide forest under different types of protection by conifers, broadleaved, total or by age, by tree composition, owners structure etc.

- Real tables

A) Protected forests by regions

construction remarks:

– **construction of this account is based on spatial overlay of geographical layers of forests derived from CLC database and protected areas in the Czech Republic layer in GIS; this is ideal way of targeted accounts construction because the statistical data can be transferred very easily into any spatial units**

– only really protected areas are calculated in the account for 1975 (that is much lower area than in 1990 because in 1990 there were designated more protected areas in the Czech Republic) – other way of calculation can be the calculation of forest area in the same territories for the both years (based of protected areas designated in final year) to find out if the forests in protected areas increased or decreased

factual remarks:

– protection of nature has undergone intensive positive development from 1975 until 1990 and further; many new protected areas have been designated and new low stated also areas (1st zones of national parks) where the forests are left to natural development and felling is not possible (forests not available for wood supply)

Figure 4.48: Forests of protected areas in the Czech Republic 1975

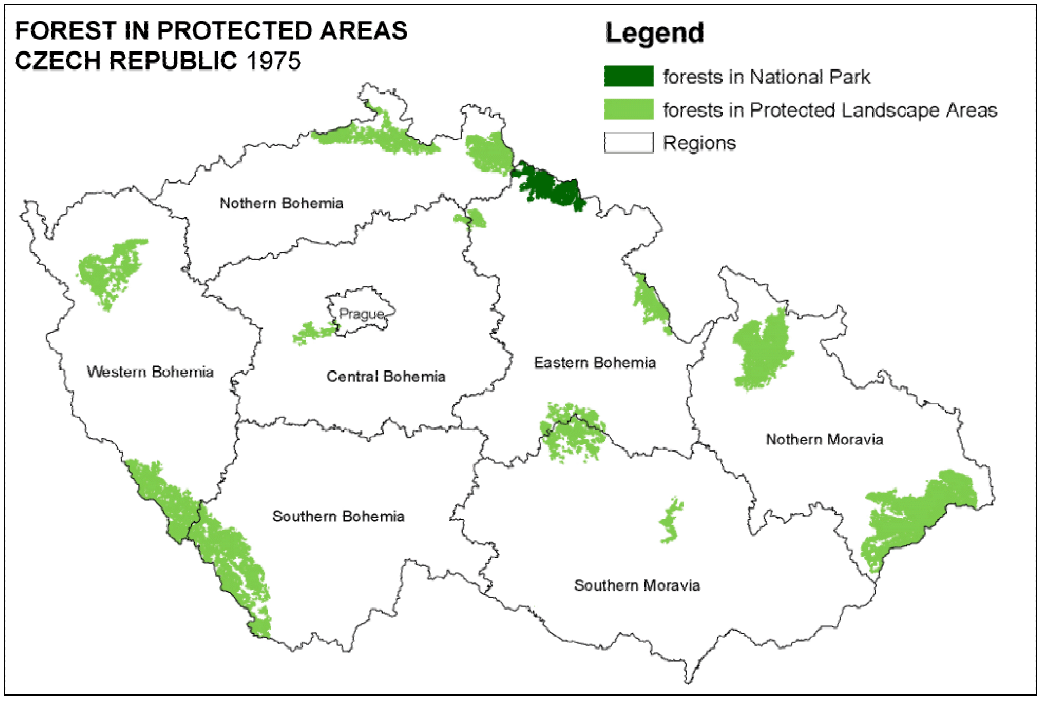


Figure 4.49: Forests of protected areas in the Czech Republic 1990

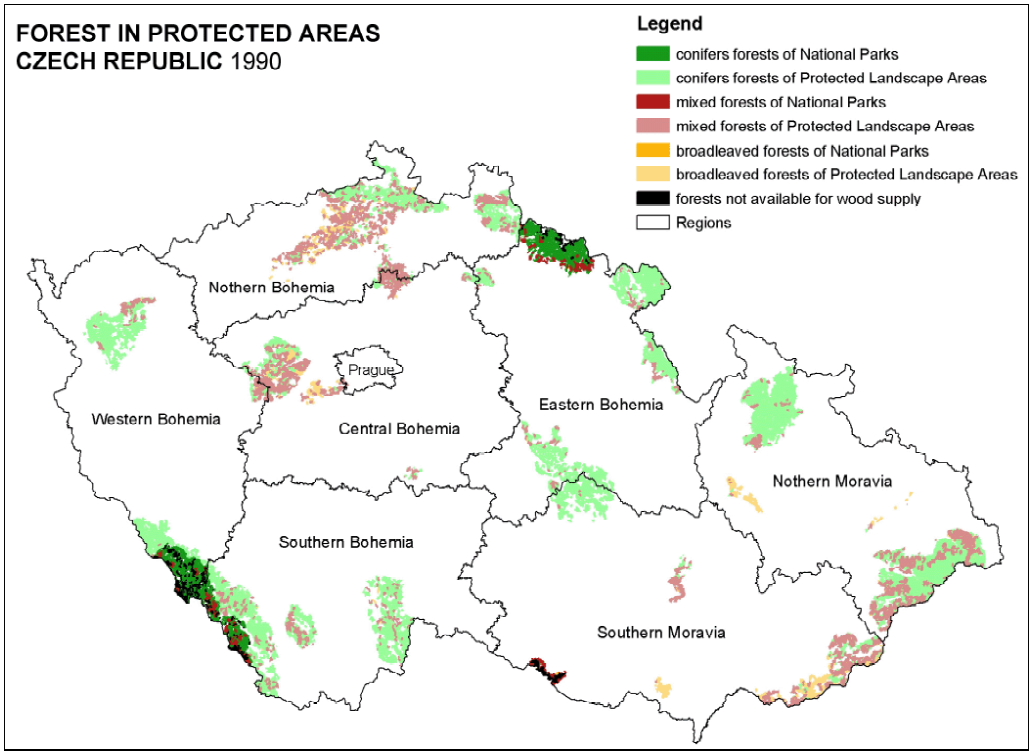


- Statistical data needs for forest protection accounts (by districts, regions, natural forest regions – NFR) – in ha

1) **areal extent of forested areas under various protection – nature, water, soil other protection, or spatial layers of protected areas**
2) **natural protection can be divided by national parks, protected landscape areas and other types of areas**
3) **forests can be divided in conifers, broadleaved, mixed, total, not available for wood supply, by age, tree species etc.**

- Theoretical proposal of account: Forests biodiversity and health by landscape types or regions or forest regions (Fig. 4.43)

construction remarks:

– construction depends on available data

factual remarks:

– biodiversity can be expressed using real current tree composition data and their comparison with natural composition

– forest health can be evaluate on special methods; CORINE data base can be used for this purpose

- Real tables

A) Forest diversity by tree species in the Czech Republic

construction remarks:

– percentage share of individual tree species on natural composition have been used to evaluate tree composition in 1975 and 1990

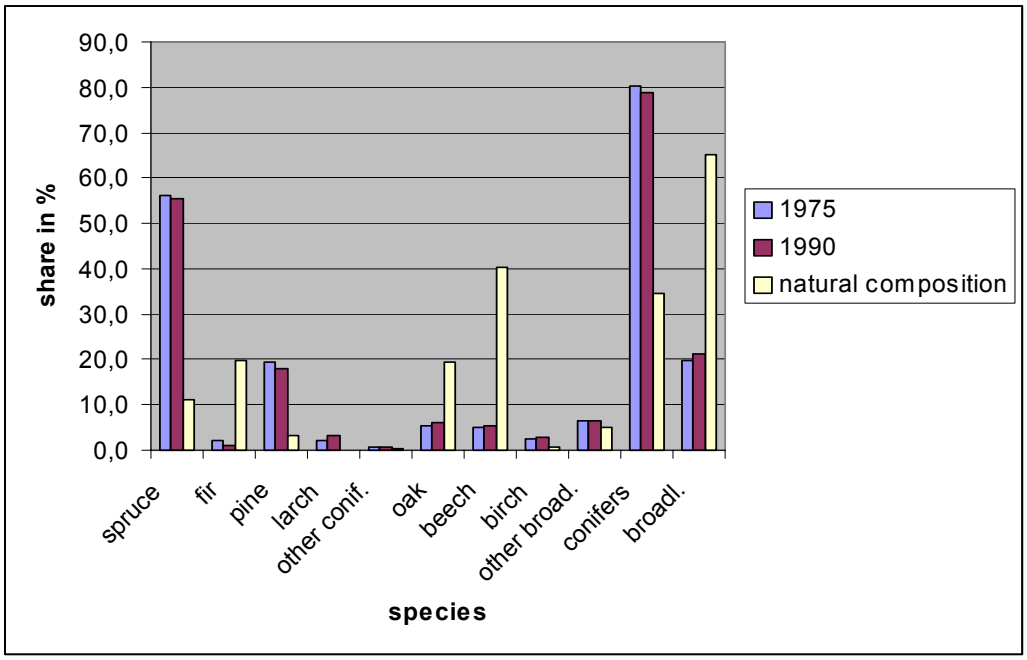
factual remarks:

– as following figure shows tree composition of forests in the Czech Republic is very far from natural composition

– the real share of conifers is much higher than their share in natural composition

– from 1975 until 1990 slight decrease of conifers and increase of broadleaved have been recorded

Figure 4.50: Comparison of forest tree composition in 1975 and 1990 with natural composition



B) Air pollution damage degree of coniferous forests in the Czech Republic

construction remarks:

– this account can be classified as a special account of forest health and forest protection because it shows the development of damage caused by air pollution – the results of the endeavour to improve the air quality and to reforest former forestland where the trees were damaged due to air pollution

factual remarks:

– in the period 1975 – 1995 the forest damage caused by air pollution continued; the development in the last decade (until 2000 or 2003) shows improvement and the decrease of forests in particular damage classes

- Statistical data needs for forests biodiversity and health accounts (by landscape types, regions, natural forest regions – NFR) – in ha

1) **real tree composition + natural tree composition**
2) **forest condition or damage data,**
3) **in the case of forest condition or damage the data can be in GIS layer format**
4) **CORINE LC data (satellite images) can be used for the evaluation (forest layer evaluation for condition or health)**

- Social accounts of forests (Fig. 4.44)

construction remarks:

– this account depends on statistical data

– because forests are irregularly dispersed in any administrative units for which social data like population or tourism income are published these statistics are hardly transferable into forest accounts

- Real tables

A) Employment by forestry in the Czech Republic

B) Export from the Czech Republic

C) Direct investments for 1 m^3 of wood

construction remarks:

– there are just very simple sporadic information available in Czech statistics for social accounts construction

factual remarks:

– the share of workers in forestry on total no. of employees is very marginal

– the Czech Republic still exports a big amount of wood just for economic benefit, it has negative influence on Czech forests

- Statistical data needs for forest composition and biodiversity accounts (by landscape types, regions, natural forest regions – NFR)

1) **employment by forestry (number of workers, share on total no. of workers)**
2) **income from forestry (by types of products, from export)**
3) **investments in forestry (by types of forest management activities)**
4) **population in forested areas (need to be recalculated from administrative units)**
5) **tourism and recreation frequentation (from special censuses)**
6) **tourism and recreation income (need to be recalculated from general tourism income for forests)**

4.4.5 List of forest statistical data that will be recorded in the Czech Republic in the future

As we mentioned above in the report there are two organizations that produce statistical data for forests in the Czech Republic – *Czech Statistical Office* and *Forest Management Institute*. We do not provide a list of forests statistics that will be published by *Czech Statistical Office.* The main reason is that these records are not at all of use for forest targeted accounting. *Czech Statistical Office* records only data for "forest land" not really "forested land" and the data are practically only on country level. There are several basic records for regional level (regions valid from 1993) but not suitable for accounting. Only interesting records in the Yearbooks of *Czech Statistical Office* are concerned with game hunting (see Fig. 4.41).

Valid and appropriate for forest accounting are forest statistics that are being produced and will be in the future produced by *Forest Management Institute*. These data will be produced

for *ntural forest regions – NFR* (see Fig. 4.31) and for administrative units on the level of *country* (NUTS 1), *groups of regions* (NUTS2), *regions* (NUTS 3 – see Fig. 4.29) and *districts* (NUTS 4 – Fig. 30).

In the following list we provide the information about data records that will be collected for different reporting units.

- Natural forest regions (from 1998 for each year)

Overview of areas (ha) – land destined for forest functions, forested land, cadastral area, % share of forests on total area of NFR, area of forest vegetation grades

Overview of areas by districts

Records about trees (48 species of trees + shrub)- representation – area (ha,%), stock (m^3 u.b., %)

Comparison of species composition (ha, %) (15 tree species + other broadleaved + other conifers + total) – real composition, targeted composition, natural composition

Composition of age groups (17 age groups) – area of age group (ha), share of age group area (%), normal distribution of age group, variance from normal composition (%)

Representation of stocks in age groups (17 age groups) – average stock (m^3/ha), share of conifers, broadleaved, total (%)

Development of anticipated growth of stocks – growth stocks (1000 m^3), average stocks (per 1 ha or m^3) in 2001, 2011 and 2021

Overview of annual increments – average clearing increment, total average increment, total increment (m^3/ha).

Overview of anticipated felling possibilities (m^3 u.b.) – 2001, 2011, 2021

Overview of forest functions in public interest (ha, %) – general protective function (4 categories), water protection (3 categories), nature preservation (6 types), health-recreational function, climatic function, landscape creation function, forests for education purpose, gene basis, territorial system of ecological stability forests, game breeding forests, other important public interest

Forests by air pollution damage classes (ha, %) – classes A, B, C, D

Overview of forests accessibility (m/1ha) – the density of road network

Representation of targeted management complexes – forested area (ha), share (%)

Basic records by forest categories

Species composition on forested land

Share of forested land and stocks on 1 inhabitant

- Administrative units – NUTS 1, 2, 3, 4 (from 1994 for each year)

Basic records by forest categories and forest functions – forested area (ha) and stocks (1000 m^3 and m^3/1 ha) for commercial forests, protection forests, special purpose forests (general protective function, water protection, nature preservation, health-recreational function, climatic function, biodiversity protection, forests for education purpose, game breeding forests, other important public interest)

Basic records by forest categories, management practice and sylvicultural system – forested area (ha), stocks – of conifers, broadleaved, total (1000 m^3)

Basic record by tree species (26 tree species + other conifers + other broadleaved + total) – forested area (ha), stocks (m^3), bonity, average age

Basic records by trees and age groups (22 tree species, 17 age groups) – forested area (ha), stocks (1000 m^3 u.b.)

Basic records by forest categories and age (17 age groups) – forested area (ha), stocks (1000 m^3 and m^3/1 ha), annual felling (1000 m^3 and m^3/1 ha), annual afforestation (ha) for commercial forests, protection forests, special purpose forests (general protective function, water protection, nature preservation, health-recreational function, climatic function, biodiversity protection, forests for education purpose, game breeding forests, other important public interest)

The list contents data that are published annually and available online on the internet. It is possible to order also other records and to pay for them. It is possible also to order spatial data (GIS layers) for natural forest regions. Suitable for forest accounting would be especially layers of NFR borders, borders of air pollution damage classes, spa forests, forests of schools, military forests, forests for research, forests near to cities and recreational forests, forests for animal breeding, protection forests, barrier forests, soil protection forests, areas of planned deforestation, productional potential of forests, index of the degree of forest naturalness from the available spatial data set.

Part 5: Contribution of forest accounting for forest indicators development

One important role of forest accounting is the use of forest stocks and flows as forest indicators. Forests indicators in general are a part of several environmental indicators sets and forest accounting can contribute to improve the ways of qualitative and quantitative forest indications used in these sets. In addition to the conventional forest accounts, the land accounts targeted to forestry integrate indicators in a broader vision of the dynamics of changes in land cover, on the one hand, and of the multiplicity of uses of the same territory (with the subsequent possible conflicts) on the other hand. Among the most developed sets of environmental indicators where forests indicators are presented belong European Environment Agency (EEA) indicators set[47], MCPFE (Ministerial Conference on the Protection of Forests in Europe) indicators set[48] and OECD indicators sets[49]. Connections of all these sets with outputs of forest accounting that are of importance for EUROSTAT are widely discussed in IEEAF (2002)[50].

IEEAF (2002) mentions that the description of other functions of forest requires the development of new statistics, in particular as concerns the classification of forests according to various criteria of quality (health, productivity, etc.) as well as ecological or recreational functions. To ensure consistency, such indicators should be based on accounting frameworks, such as material flow accounts, changes in quality accounts, etc

According to IEEAF (2002) through quantitative (or qualitative) changes in assets (and corresponding changes in value, when monetary values are assessed), accounting approach permits to relate opening and closing stocks of forest related assets with the pressures exerted by economic activities. It would thus allow linking forests indicators with the system of national accounts, giving them a coherent basis in order to identify and assess appropriate economic instruments and policies. Moreover some types of accounts could be necessary in order to assess the progress towards sustainable management of forests. For example some indicators from above mentioned sets refer to changes in the proportion of forest area

managed primarily for soil and water protection or to changes in the area of forests protected by special management regime. And these are records that can be obtained from forest accounts (targeted accounts).

As an output from LEAC two main types of forest indicators can be constructed – indicators based on basic accounts or land cover flows (LCF) and indicators based on targeted forest accounts. As an output from our project we suggested some simple indicators based on LCF and targeted forest accounts and calculated their values for 4 CE studied countries, for regions in the Czech Republic and for districts in Northern Bohemia region. The differences in the results of these three levels show the importance of the reporting level unit selection for the regional differentiation of the indicated phenomenon.

5.1 Indicators based on basic accounts or LCF

- Change of forested area – **FA_{ch}** (in %)

Description: percentage change of forested area (CORINE LC category 31) in defined period.

Formula is like:

EQUATION $FA_{ch}=F_2/F_1*100$

where: F_1 is forested area in first year, F_2 is forested area in second year under observation.

Range of values: FA_{ch} – value 100 means no change, values below 100 mean decrease of forested land in the defined period, values over 100 mean increase of forested land.

Figure 5.1: FA_{ch} 1975-1990 in study areas

	Study area	FA_{ch} (%)
region in the Czech Republic	Prague	100.57
	Central Bohemia	95.70
	Southern Bohemia	93.68
	Western Bohemia	92.65
	Northern Bohemia	68.14
	Eastern Bohemia	97.74
	Southern Moravia	95.84
	Northern Moravia	97.62
district in Norther Bohemia	Chomutov – CV	60.85
	Louny – LN	94.23
	Most – MO	71.86
	Teplice – TP	75.80
	Litoměřice – LT	96.26
	Ústí nad Labem – UL	93.86
	Děčín – DE	92.53
	Česká Lípa – CL	93.90
	Liberec – LB	89.98
	Jablonec – JN	82.16
Country	The Czech Republic	94.55
	Slovakia	95.60
	Hungary	98.44
	Romania	98.48

Figure 5.2: FA_{ch} 1975-1990 in the Czech Republic, Hungary, Romania and Slovakia

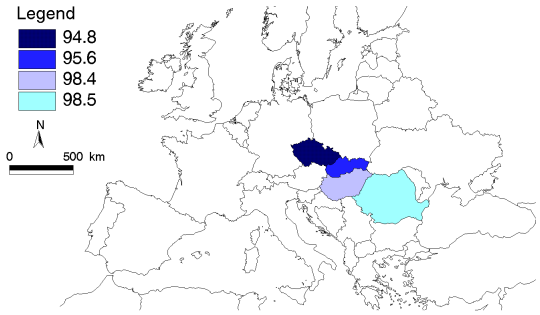

Figure 5.3: FA_{ch} 1975-1990 in regions of the Czech Republic

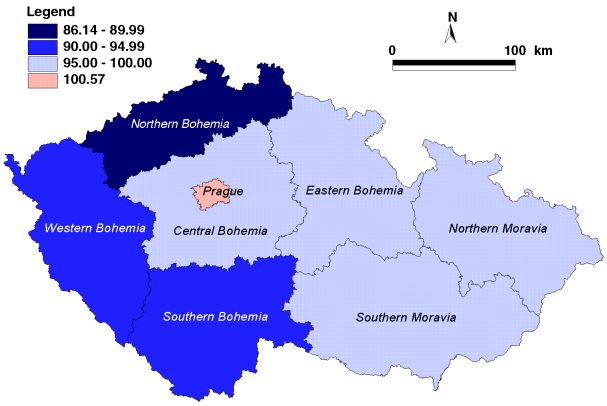

Figure 5.4: FA_{ch} 1975-1990 in the districts of Northern Bohemia

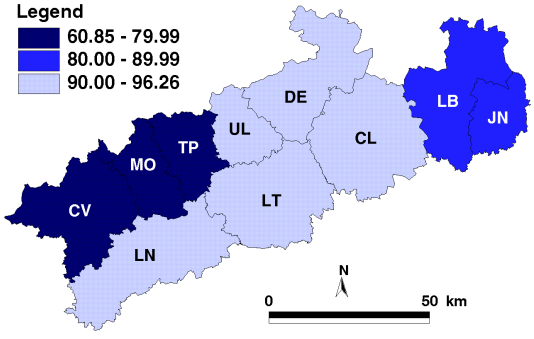

- Rate of afforestation due to agricultural extensification – **RAF** (in %)

Description: this indicator assets rate of afforestation due to agricultural extensification. If changes of forests into agriculture land are lower than changes of agricultural land into forests the value is negative (it means that the process is opposite – deforestation due to agricultural intensification). The indicator is concerned only with agricultural and forest land mutual changes, and it does not testify about total afforestation or deforestation, respectively about total extensification or intensification of agriculture.

Formula is like:

EQUATION $RAF= (C_1-C_2)/(A+F)*100$

where C_1 are changes (flows) of CORINE LC categories of agricultural land (21, 22, 23, 24) into forests (category 31), C_2 are changes (flows) of forests (31) into agricultural land categories during the period under observation, A is total area of agricultural land (21+22+23+24) in the first year of the period under observation and F is total area of forest land in the first year of the period under observation.

Range of values: from 100% until (–100%). Value 0 means that the same area of forests has been changed into agricultural land as the area of agricultural land that has been changed into forest, or no change. Values higher 0 mean afforestation due to agricultural extensification, values lower 0 mean deforestation due to agriculture intensification

This indicator will be very relevant for CEE countries in the period of their transformation because CE countries in comparison with WE countries have very high share of agricultural land (especially arable land) and a part of it has been determined for afforestation. Even state subsidies are provided for the purpose of agricultural land afforestation. So this indicator can follow the development of the process. It is important that the afforestation due to agricultural extensification (values higher 0) leads to the increase of area of more natural ecosystems – forest ecosystems – in the landscape and the condition and stability of landscape is increasing this way. This indicator can express direct results of current driving forces in CE countries in the last decade of 20^{th} century and further. Anyway for the period 1975-1990 RAF is mostly negative (it means deforestation due to agricultural intensification prevailed).

5.2 Indicators based on targeted forest accounts

Many of forest accounts proposed in SEEA2003[51] or in IEEAF (2002)[52] can be directly used for indication of forest state and development (quantitative and also qualitative). These are for example accounts concerned with forest age structure, biodiversity (tree composition), forests under individual types of protection, management practices of forests. Some of these accounts are also a part of our set of targeted accounts (see chapter 4). We used one of the proposed targeted accounts for the attempt to more improve and simplify the indication possibility (potential) of its phenomenon – of tree composition (see the following proposed indicator).

- Naturalness of forest tree composition – **NTC**

description: the indicator compares real tree composition in the certain year with potential natural composition on the level of country (region, forest type etc.)

Figure 5.6: Naturalness of forest tree composition in the Czech Republic 1975, 1990

	spruce	fir	pine	larch	other conifers	oak	beech	birch	other broadleaved	NATURALNESS in p.p.	conifers	broadleaved
natural composition (%)	11.2	19.8	3.4	0.0	0.3	19.4	40.2	0.8	4.9	100	34.7	65,3
share 1975 (%)	56.0	2.1	19.3	2.2	0.6	5.5	5.0	2.6	6.5		80.3	19.7
share1990 (%)	55.6	1.1	18.1	3.3	0.8	6.1	5.5	2.9	6.6		78.9	21.1
natural 1975	11.2	2.1	3.4	0.0	0.3	5.5	5.0	0.8	4.9	33.2		
natural 1990	11.2	1.1	3.4	0.0	0.3	6.1	5.5	0.8	4.9	33.3		

advantages of the indicator:

– easy calculable indicator when the data set is available

disadvantages of the indicator:

– the changes of total forested area during time

– changes in forest location – forests partly covered different areas in the past and the current tree composition can be to a certain level influenced by the changes in the location.

Basic accounts and LCF are good data sources for further development of environmental indicators in general (not indicators only for forests). There are some preliminary ideas but it is not a subject of this study. Using satellite images data (that are inputs for CORINE LC

---

[51] Handbook of National Accounting.Integrated Environmental and Economic Accounting 2003, ST/ESA/STAT/SER.F/61/Rev.1 (Final Draft)

[52] The European Framework for Integrated Environmental and Economic Accounting for Forests- IEEAF. Luxembourg: Office for Official Publications of the European Communities, 2002, Cat. No. KS-BE-02-003-EN-N

classifications) it is also possible to develop in the future indicators of qualitative state of forests – forest condition or health. It means that with specific methods of classification can be CORINE LC database information potential further used for forest and other environmental indicators development.

Discussion and conclusions

The analysis of the data needed for LEAC has shown a number of data gaps or data limitations in available data sources.

First, in case of CORINE Land Cover data for 1975, the nomenclature was available on level 2 only. Although, surprisingly this was not such an issue during general basic accounts creation, where it didn't represent a serious limitation, the lost of internal rotation flows (in particular forest ones) caused a serious problem in construction of targeted accounts and made impossible to access certain processes related to tree composition development and its influence on biodiversity change. Therefore, some of the topics planned had to be modified and some outputs had to be simplified according to level 2 contents. In this line, the I&CLC 2000 update brings a new perspective, as this problem will be eliminated and comparisons of 1990 and 2000 are to be carried out on the level 3.

Still, the study has indicated that, in case of initial stock, the aggregated CLC classification on level 2, extended to several classes e.g. 213, 243 and forest classes 311, 312, 313 (CLC Level 2bis), would allow to trace most of the land cover flows, as defined in this study, completely. This finding can be interesting message for future planning of country or European wide retrospective CLC inventories. Retrospective CLC inventories usually demand extensive ancillary information support for interpretation of old satellite data or aerial photos, which represent a serious limitation due to restricted availability and cost of such information. Aggregated CLC nomenclature (e.g. from level 3 to level 2bis) could help reducing this demand.

Problems with availability of other types of data as NATURA2000, detailed administrative boundaries or European Grid have been discussed in the coastal study already.

As for statistical data significant problem that should be preferentially solved by EUROSTAT in co-operation with national statistical offices and other data collecting organizations in individual countries is the lack of statistical data suitable for forest targeted accounts, especially on regional and lower levels and for natural reporting units. The situation in the Czech Republic, where the case study concerned with forest targeted accounts has been processed, was in both studied years 1975 and 1995 very bad. The problem is not just in data lack on the regional and district levels but also in the thematic incompatibility of the data – different types of records, different units (ha x m^3) etc. Other serious problem is that especially in 1975 the statistical data in general level were often modified – misrepresented because of political reasons. For these reasons we were able to collect just several identical forest data records for 1975 and 1990 on country and regional levels and to construct simplified targeted accounts. Though the situation of forest statistical data collection has been improved, especially from 1994, there are still data gaps that should be solved. For the possible CORINE classifications from 2000 and targeted forest accounts constructed for the period 1990 – 2000 the problems with forest statistical data lack will partly continue because the new suitable data records has been stored only from 1994 for administrative units and even only from 1998 for natural forest regions.

Because forests ecosystems are “natural units” it is more appropriate to present forest accounts by some type of natural (relatively naturally defined) reporting units. In this study, we present accounts of forest flows by defined landscape types. In future, perspective reporting units in the Czech Republic seem to be natural forest regions (NFR) for which the forest statistics will be collected in the future. The advantage of these units is that they are directly connected with forests, so the statistical data need not to be redistributed (except population statistics that is not collected for NFR). Relation of NFR to dominant landscape types will be investigated, too. The redistribution of the social data into natural units is other methodological task, but the CLC data could serve as a mediator here. However, it couldn’t be proved in our study, due to the data lack on the appropriate reporting level used for the data redistribution (for example district level – the data for it are collected only from 1994).

Due to available land cover data, the study covered the period of 1975-1990 years. Almost at the end of this 15 years long period all studied CEE countries undergone significant political breakdown and immediately economic and social conditions started to change. Especially the conditions of market economy, private property and changes in land protection caused significant changes of land use and landscape cover on their territories. The main economic driving forces in the Czech Republic, Slovakia, Hungary and Romania before 1989 were an absence of private property, centrally governed national economy (5 years plans), socialistic regime oriented on communist propaganda (“economic wealth” as a result of socialism). Important driving force in the Czech Republic as for forestry and landscape management was also strict preservation of agricultural land that could not be used for constructions or changed for meadows and forests. Very important driving force that influenced forests in the Czech Republic was energy conception based on brown coal power plants that produced high amount of emissions that caused very extensive forest damage in Northern and Eastern Bohemia. As a main impacts of these driving forces in the Czech Republic can be mentioned poor forest management, maximalization of wood production on the sake of forest stability, die of forest weakened by air pollution or such a problem like poor and misrepresented forest statistics.

Poor forest management (collective property management is always worse than the care for private property) have resulted for example in very unfavourable age structure that testify targeted account – Fig. 4.38 A, further in very transformed adverse tree composition that is evident from targeted table – Fig. 4.43 A. This tree composition is not a result just of socialist period, the contrary changes started earlier but during the socialist period the production goals still prevailed and the interests of forest ecosystems stability and biodiversity preservation were not accepted. It is also confirmed in targeted account of forest protection (Fig. 4.42 A) that shows the big difference of the preserved forests area in 1975 and 1990. Clear felling practice in forest management is an example of low quality management practice. They have resulted in not stable and not resistant one-age even growths that could be easily damaged by wind or insect calamities. Special case where the impacts of poor management and socialistic energy conception without preservation of environment were cumulated resulted in the extensive forest decline due to air pollution. Targeted account concerned with damage of conifers forests (Fig. 4.43 B) is clear evidence how extensive areas of forests have been damaged. All mentioned impacts resulted in total area forest decline in the Czech Republic during the period under observation. Societal response on these alarming unfavourable changes in forest state and condition came only with the change of political system and economic transformation after 1989.

Despite of some problems with data resources and the specifics of the period selected for the 4 CEE countries study, as discussed above, number of interesting results have been achieved in contribution to further LEAC development, both on level of the basic and the targeted account.

The CORILIS based methodology for creation of dominant landscape types has been tested for four countries with distinct landscape pattern and the results have shown its feasibility and flexibility to support country or European wide LEAC creation. More complex elevation breakdown has been introduced into the landscape types to cover mountain areas to allow further assessment according EU regulations. Definition of land cover flows (LCF) has been revised and further enhanced to trace better land cover processes. Also LCF has been adapted and make compatible for the CLC data available with reduced nomenclature as discussed above. Based on these developments the most significant and interesting result is the full set of basic accounts prepared for the 4 CEE countries allowing future extensive analysis.

Concerning targeted forest accounts as the most significant and interesting result can be considered the presented tables including the theoretical proposals, remarks and comments for individual accounts, data needs lists and the list of the forest statistical data that will be recorded in the Czech Republic in the future. These outputs are a good base not only for further methodological and forest (influence of socio-economic development on forests) research but also for practical use in EUROSTAT future work and projects concerned with forest accounting. Especially the listings of statistical data needs for each proposed accounts are in general level applicable not only in the Czech Republic but the same data should be available for forest targeted accounting in any country or area of interest. Important finding is also that spatial GIS layers with forest statistical attributes (like layer of preserved areas) can be used with advantage for the accounting in different (especially natural) reporting units on various levels.

Proposed forest indicators can contribute for forest quantity (area development) and quality (forest composition) monitoring. In the next period, especially the RAF indicator (Rate of afforestation due to agricultural extensification) can be useful in the monitoring of agricultural extensification during the process of the studied countries accession with EU.

Future development in area of the basic accounts will concentrate on further development in result presentation and development of other “zoning” options. As for targeted accounting methodology it will be important to develop and improve methods of statistical data redistribution from administrative into natural units, to start wider discussion of Eurostat with national statistical offices and other organizations that record statistical data about forest data needs for targeted accounting, to develop further forest targeted accounts based on better statistical sources that will be more appropriate also for forest and biodiversity indicators construction.

Finally, we consider that, in all CEE countries, recent changes like return of private property (restitutions), market economy rules, agriculture extensification, new land preservation law (less strict) or new natural protection law are the main driving forces that govern the impacts on forests, forestry and landscape stability at all from 1990. It will be possible to testify their impacts during the last decade, when results from the I&CLC2000 project are available, by targeted forest accounts constructed for the period 1990–2000. Therefore, updated CORINE Land Cover data and proposed LEAC methodology can bring this way interesting comparison of the influence of socio-economic changes on the landscape during 1975-1990 and during 10

years of transformation in 1990-2000. In longer perspective it can serve as base for LEAC supported scenario development.

ANNEXES

ANNEX 1: Correspondence matrix between land cover changes (CLC level2 /level 3) and the land cover flows

ANNEX 2: Comparison of the LCF figures produced using level2/level3 and level3/level3 matrix based definitions
Note: based on the CLC1990/2000 data for the Netherlands

ANNEX 3: Basic Accounts for the Czech Republic

ANNEX 4: Basic Accounts for the 4 CEE countries
Note: selected set only for country accounts of Hungary, Romania and Slovakia. Full set is available in digital.

ANNEX 1: Correspondance matrix between land cover changes (clc level2 /level 3) and the land cover flows

CORRESPONDANCE BETWEEN LAND COVER CHANGES (CLC LEVEL2 vs. CLC LEVEL 3) AND THE LAND COVER FLOWS (LCFs)
